- ABSTRACT**

- The electrical characteristics of a transistor including an oxide semiconductor layer are varied by influence of an insulating film in contact with the oxide semiconductor layer, that is, by an interface state between the oxide semiconductor layer and the insulating film. A first oxide semiconductor layer S1, a second oxide semiconductor layer S2, and a third oxide semiconductor layer S3 are sequentially stacked, so that the oxide semiconductor layer through which carriers flow is separated from the gate insulating film containing silicon. The thickness of the first oxide semiconductor layer S1 is preferably smaller than those of the second oxide semiconductor layer S2 and the third oxide semiconductor layer S3, and is less than or equal to 10 nm, preferably less than or equal to 5 nm.

SEMICONDUCTOR DEVICE INCLUDING OXIDE SEMICONDUCTOR LAYER

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a semiconductor device including an oxide semiconductor and a manufacturing method of the semiconductor device.

In this specification, a semiconductor device means a device which can function by utilizing semiconductor characteristics, and an electrooptic device, a semiconductor circuit, and an electronic device are all semiconductor devices.

2. Description of the Related Art

In recent years, semiconductor devices have been developed to be used mainly for an LSI, a CPU, or a memory. A CPU is an aggregation of semiconductor elements each provided with an electrode which is a connection terminal, which includes a semiconductor integrated circuit (including at least a transistor and a memory) separated from a semiconductor wafer.

A semiconductor circuit (IC chip) of an LSI, a CPU, or a memory is mounted on a circuit board, for example, a printed wiring board, to be used as one of components of a variety of electronic devices.

A technique for manufacturing a transistor by using an oxide semiconductor film for a channel formation region, or the like has been attracting attention. Examples of such a transistor include a transistor in which zinc oxide (ZnO) is used as an oxide semiconductor film and a transistor in which $\text{InGaO}_3(\text{ZnO})_m$ is used as an oxide semiconductor film. A technique in which a switching element, such as a transistor, in which a channel formation region is formed in an oxide semiconductor film is used for manufacturing an active matrix display device has also been developed.

Patent Document 1 discloses a three-layer structure in which a first multi-component oxide semiconductor layer is provided over a substrate, a one-component oxide semiconductor layer is stacked over the first multi-component oxide semiconductor layer, and a second multi-component oxide semiconductor layer is stacked over the one-component oxide semiconductor layer.

Non-Patent Document 1 discloses a transistor having a stack of oxide semiconductors.

SUMMARY OF THE INVENTION

The electrical characteristics of a transistor including an oxide semiconductor layer are varied by influence of an insulating film in contact with the oxide semiconductor layer, that is, by an interface state between the oxide semiconductor layer and the insulating film.

For example, interface scattering of carriers at the interface between the oxide semiconductor layer and the insulating

2

layer in contact with the oxide semiconductor layer causes degradation of the field-effect mobility of the transistor. Moreover, if a trap level (also referred to as an interface state) exists at that interface, the trap level causes a change in the electrical characteristics (e.g., the threshold voltage, the sub-threshold swing (S value), or the field-effect mobility) of the transistor.

An object of one embodiment of the present invention is to provide a structure of a transistor having high field-effect mobility.

Another object of one embodiment of the present invention is to provide a highly reliable semiconductor device including an oxide semiconductor by preventing a change in its electrical characteristics.

Thus, in order that an oxide semiconductor layer through which carriers flow is not in contact with a gate insulating film containing silicon, a structure in which the oxide semiconductor layer through which carriers flow is separated from the gate insulating film containing silicon is employed.

Specifically, a first oxide semiconductor layer S1, a second oxide semiconductor layer S2, and a third oxide semiconductor layer S3 are sequentially stacked, so that a structure having an energy band diagram (which is a schematic diagram) shown in FIG. 1B is formed. In the energy band diagram shown in FIG. 1B, the energy level of the bottom of the conduction band in the second oxide semiconductor layer S2 is lower than those of the bottoms of the conduction band in the first oxide semiconductor layer S1 and the third oxide semiconductor layer S3. Further, the energy band diagram preferably has a round well structure in which the energy of the bottom of a conduction band is continuously changed to the energy of the bottom of an adjacent conduction band.

A structure of one embodiment of the present invention disclosed in this specification is a semiconductor device including a first insulating layer over an insulating surface, a first oxide semiconductor layer over the first insulating layer, a second oxide semiconductor layer over the first oxide semiconductor layer, a third oxide semiconductor layer over the second oxide semiconductor layer, and a second insulating layer over the third oxide semiconductor layer. At the interface between the second oxide semiconductor layer and the first oxide semiconductor layer and in the vicinity of the interface, the energy of the bottom of the conductive band of the first oxide semiconductor layer is continuously changed to the energy of the bottom of the conductive band of the second oxide semiconductor layer. In other words, the energy of the bottom of the conduction band of the first oxide semiconductor layer S1 is connected to the energy of the bottom of the conduction band of the second oxide semiconductor layer S2 at the interface between the first oxide semiconductor layer S1 and the second oxide semiconductor layer S2 and in the vicinity of the interface, so that a curved band diagram shown in FIG. 1B is made. This is because the second oxide semiconductor layer S2 contains an element common to the first oxide semiconductor layer S1, and oxygen moves between the first oxide semiconductor layer S1 and the second oxide semiconductor layer S2 to form a mixed layer. On the other hand, in the case where the energy of the bottom of the conduction band of a layer is not continuously changed to the energy of the bottom of the conduction band of another layer at the interface between the two layers and in the vicinity of the interface, the energy level is steeply changed so that a step-like band diagram is made.

In the above structure, it is preferable that materials and compositions of the second oxide semiconductor layer and the third oxide semiconductor layer be adjusted so that the energy of the bottom of the conductive band of the second

oxide semiconductor layer is continuously changed to the conductive band of the third oxide semiconductor layer at the interface between the second oxide semiconductor layer and the third oxide semiconductor layer and in the vicinity of the interface.

Further, in the above structure, the composition of the second oxide semiconductor layer is different from those of the first and third oxide semiconductor layers.

As a material of the first oxide semiconductor layer S1, a material which can be represented as $M1_aM2_bM3_cO_x$ (a is a real number greater than or equal to 0 and less than or equal to 2, b is a real number greater than 0 and less than or equal to 5, c is a real number greater than or equal to 0 and less than or equal to 5, and x is an arbitrary real number) is used. Ga, Mg, Hf, Al, Zr, Sn, or the like can be used as the constituent element M2 to function as a stabilizer for reducing the number of oxygen vacancies in an oxide semiconductor. As another stabilizer, one or plural kinds of lanthanoid such as lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), samarium (Sm), europium (Eu), gadolinium (Gd), terbium (Tb), dysprosium (Dy), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), or lutetium (Lu) may be contained. As the constituent element M1, indium or the like is used. As the constituent element M3, zinc or the like is used.

Typically, for the first oxide semiconductor layer S1, a gallium oxide film, a gallium zinc oxide film, or a material film in which the content of the constituent element M2 is higher than the content of the constituent element M1 is used. For example, an In—Ga—Zn-based oxide film which is deposited using a sputtering target having any of atomic ratios of In:Ga:Zn=1:3:2, In:Ga:Zn=1:4:2, and In:Ga:Zn=1:5:4 is used. In forming the first oxide semiconductor layer, deposition is preferably performed by a sputtering method in a mixed atmosphere containing more oxygen than a rare gas and more preferably in an oxygen atmosphere (oxygen: 100%), and the resulting oxide semiconductor layer can also be referred to as a first I-type oxide semiconductor layer. The first I-type oxide semiconductor layer is a highly purified oxide semiconductor layer that contains impurities other than the main components of the oxide semiconductor layer as little as possible and is an I-type (intrinsic) oxide semiconductor or close thereto. In such an oxide semiconductor layer, the Fermi level (E_f) can be at the same level as the intrinsic Fermi level (E_i).

Further, the thickness of the first oxide semiconductor layer S1 is preferably smaller than those of the second oxide semiconductor layer S2 and the third oxide semiconductor layer S3, and is less than or equal to 10 nm, preferably less than or equal to 5 nm.

For the second oxide semiconductor layer S2, a material which can be represented as $M4_dM5_eM6_fO_x$ (d is a real number greater than 0 and less than or equal to 5, e is a real number greater than or equal to 0 and less than or equal to 3, f is a real number greater than 0 and less than or equal to 5, and x is an arbitrary positive number) is used. Ga, Mg, Hf, Al, Zr, Sn, or the like can be used as the constituent element M5 to function as a stabilizer for reducing the number of oxygen vacancies in an oxide semiconductor. As another stabilizer, one or plural kinds of lanthanoid such as lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), samarium (Sm), europium (Eu), gadolinium (Gd), terbium (Tb), dysprosium (Dy), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), or lutetium (Lu) may be contained. As the constituent element M4, indium or the like is used. As the constituent element M6, zinc or the like is used. Typically, a material film in which the content of the constituent element M4 is higher than the content of the constituent element M5 is used. For

example, an In—Ga—Zn-based oxide film which is deposited using a sputtering target having an atomic ratio of In:Ga:Zn=3:1:2 is used. In forming the second oxide semiconductor layer, deposition is preferably performed by a sputtering method in a mixed atmosphere containing more oxygen than a rare gas and more preferably in an oxygen atmosphere (oxygen: 100%), and the resulting oxide semiconductor layer can also be referred to as a second I-type oxide semiconductor layer. The second I-type oxide semiconductor layer is a highly purified oxide semiconductor layer that contains impurities other than the main components of the oxide semiconductor layer as little as possible and is an I-type (intrinsic) oxide semiconductor or close thereto. In this manner, the Fermi level (E_f) can be equal to the intrinsic Fermi level (E_i).

For the third oxide semiconductor layer S3, a material which can be represented as $M7_gM8_hM9_iO_x$ (g is a real number greater than or equal to 0 and less than or equal to 2, h is a real number greater than 0 and less than or equal to 5, i is a real number greater than or equal to 0 and less than or equal to 5, and x is an arbitrary real number) is used. Ga, Mg, Hf, Al, Zr, Sn, or the like can be used as the constituent element M8 to function as a stabilizer for reducing the number of oxygen vacancies in an oxide semiconductor. As another stabilizer, one or plural kinds of lanthanoid such as lanthanum (La), cerium (Ce), praseodymium (Pr), neodymium (Nd), samarium (Sm), europium (Eu), gadolinium (Gd), terbium (Tb), dysprosium (Dy), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), or lutetium (Lu) may be contained. As the constituent element M7, indium or the like is used. As the constituent element M9, zinc or the like is used. Typically, a material film in which the content of the constituent element M7 is substantially equal to the content of the constituent element M8 is used. For example, an In—Ga—Zn-based oxide film which is deposited using a sputtering target having an atomic ratio of In:Ga:Zn=1:1:1 is used. In forming the third oxide semiconductor layer, deposition is preferably performed by a sputtering method in a mixed atmosphere containing more oxygen than a rare gas and more preferably in an oxygen atmosphere (oxygen: 100%), and the resulting oxide semiconductor layer can also be referred to as a third I-type oxide semiconductor layer.

In the case of a bottom-gate transistor, a gate electrode layer is provided between the insulating surface and the first insulating layer in the above structure.

On the other hand, in the case of a top-gate transistor, a gate electrode layer is provided over the second insulating layer in the above structure.

Further, in the case of a dual-gate transistor including gate electrode layers over and below the first, second, and third oxide semiconductor layers, a first gate electrode layer is provided between the insulating surface and the first insulating layer, and a second gate electrode layer is provided over the second insulating layer in the above structure.

The first, second, or third oxide semiconductor layer is in a single crystal state, a polycrystalline (also referred to as polycrystal) state, an amorphous state, or the like.

The first, second, or third oxide semiconductor layer is preferably a c-axis aligned crystalline oxide semiconductor (CAAC-OS) film.

The CAAC-OS film is not completely single crystal nor completely amorphous. The CAAC-OS film is one of oxide semiconductor films having a plurality of c-axis aligned crystal parts. In a transmission electron microscope (TEM) image of the CAAC-OS film, a boundary between crystal parts, that is, a grain boundary is not clearly observed. Thus, in the CAAC-OS film, a reduction in electron mobility due to the grain boundary is less likely to occur. From the results of the

cross-sectional TEM image and the plan TEM image, alignment is found in the crystal parts in the CAAC-OS film. Most of the crystal parts included in the CAAC-OS film each fit inside a cube whose one side is less than 100 nm. Thus, there is a case where a crystal part included in the CAAC-OS film fits a cube whose one side is less than 10 nm, less than 5 nm, or less than 3 nm. Note that when a plurality of crystal parts included in the CAAC-OS film are connected to each other, one large crystal region is formed in some cases. For example, a crystal region with an area of 2500 nm² or more, 5 μm² or more, or 1000 μm² or more is observed in some cases in the plan TEM image.

In each of the crystal parts included in the CAAC-OS film, a c-axis is aligned in a direction parallel to a normal vector of a surface where the CAAC-OS film is formed or a normal vector of a surface of the CAAC-OS film, triangular or hexagonal atomic arrangement which is seen from the direction perpendicular to the a-b plane is formed, and metal atoms are arranged in a layered manner or metal atoms and oxygen atoms are arranged in a layered manner when seen from the direction perpendicular to the c-axis. Note that, among crystal parts, the directions of the a-axis and the b-axis of one crystal part may be different from those of another crystal part. In this specification, a simple term "perpendicular" includes a range from 85° to 95°. In addition, a simple term "parallel" includes a range from -5° to 5°.

In the CAAC-OS film, distribution of crystal parts is not necessarily uniform. For example, in the formation process of the CAAC-OS film, in the case where crystal growth occurs from a surface side of the oxide semiconductor film, the proportion of crystal parts in the vicinity of the surface of the oxide semiconductor film is higher than that in the vicinity of the surface where the oxide semiconductor film is formed in some cases. Further, when an impurity is added to the CAAC-OS film, the crystal part in a region to which the impurity is added becomes amorphous in some cases.

Since the c-axes of the crystal parts included in the CAAC-OS film are aligned in the direction parallel to a normal vector of a surface where the CAAC-OS film is formed or a normal vector of a surface of the CAAC-OS film, the directions of the c-axes may be different from each other depending on the shape of the CAAC-OS film (the cross-sectional shape of the surface where the CAAC-OS film is formed or the cross-sectional shape of the surface of the CAAC-OS film). Note that when the CAAC-OS film is formed, the direction of c-axis of the crystal part is the direction parallel to a normal vector of the surface where the CAAC-OS film is formed or a normal vector of the surface of the CAAC-OS film. The crystal part is formed by film formation or by performing treatment for crystallization such as heat treatment after film formation.

During deposition, fine sputtering particles fly from a sputtering target, and a film is formed so that the sputtering particles adhere onto the deposition-target substrate. When the temperature of the substrate is higher than or equal to 200° C., the sputtering particles are rearranged because the substrate is heated. Thus, a dense film is formed.

A phenomenon in the deposition is described in detail using FIGS. 16A to 16C, FIGS. 17A and 17B, and FIGS. 18A to 18C.

When ions collide with the surface of the sputtering target, the crystal region included in the sputtering target is cleaved along an a-b plane, and sputtered particles whose top and bottom surfaces are each aligned with a layer parallel to the a-b plane (flat-plate-like sputtered particle or pellet-like sputtered particle) are separated from the sputtering target. Assuming that the crystalline particle which is sputtered from

a surface of a sputtering target **2002** and released has c-axis alignment and is a flat-plate-like sputtered particle **2001** as illustrated in FIG. 16A, a schematic model diagram in FIG. 16B can be obtained. The flat-plate-like sputtered particle is preferably a (Ga or Zn)O plane as illustrated in FIG. 16C.

When the oxygen flow rate is high and the pressure in a chamber **2003** is high during deposition, as illustrated in FIG. 17A, oxygen ions are attached onto the flat-plate-like sputtered particle and the sputtered particle can have a large amount of oxygen on its surface. Another flat-plate-like sputtered particle is stacked thereover before the attached oxygen is released; therefore, as illustrated in FIG. 18C, a large amount of oxygen can be contained in the film. This adsorbed oxygen contributes to a reduction in oxygen vacancies in the oxide semiconductor.

To form an oxide semiconductor film including a crystal region with c-axis alignment, the substrate temperature in film formation is preferably increased. However, when the substrate temperature is higher than 350° C., the adsorbed oxygen might be released as illustrated in FIG. 17B. Accordingly, the substrate temperature is set to be higher than or equal to 150° C. and lower than or equal to 350° C., preferably higher than or equal to 160° C. and lower than or equal to 230° C., and an oxygen gas is used alone as the deposition gas, whereby an oxide semiconductor film including a crystal region with c-axis alignment, i.e., a CAAC-OS film can be formed.

FIG. 18A is a model of a process in the deposition, in which one flat-plate-like sputtered particle reaches a surface of a substrate **2000** to be stabilized. As illustrated in FIG. 18A, the flat-plate-like sputtered particle reaches the substrate surface with its crystalline state maintained; thus, a CAAC-OS film is likely to be formed. Further, flat-plate-like sputtered particles are stacked as illustrated in FIG. 18B; thus, a CAAC-OS film is likely to be formed. Note that a CAAC-OS film is a film which contains much oxygen as illustrated in FIG. 18C and in which oxygen vacancies are reduced.

In the CAAC-OS film over the substrate **2000**, about 2 to 20 indium atoms are aligned in a lateral direction to form a layer including indium atoms. Note that in the layer including indium atoms, more than 20 indium atoms are aligned in a lateral direction in some cases. For example, more than or equal to 2 to fewer than or equal to 50 indium atoms, more than or equal to 2 to fewer than or equal to 100 indium atoms, or more than or equal to 2 to fewer than or equal to 500 indium atoms may be aligned in a lateral direction.

Layers including indium atoms overlap with each other. The number of layers is greater than or equal to 1 and less than or equal to 20, greater than or equal to 1 and less than or equal to 10, or greater than or equal to 1 and less than or equal to 4.

As described above, a stack of the layers including indium atoms often appears to be a cluster including several indium atoms in a lateral direction and several layers in a longitudinal direction. This is because each of the sputtering particles has a flat-plate-like shape.

At least for the second oxide semiconductor layer, the CAAC-OS film is preferably used.

For the deposition of the CAAC-OS film, the following conditions are preferably used.

Reduction in the amount of impurities entering the CAAC-OS layer during the deposition can prevent the crystal state from being broken by the impurities. For example, impurities (e.g., hydrogen, water, carbon dioxide, or nitrogen) which exist in the deposition chamber may be reduced. Furthermore, impurities in a deposition gas may be reduced. Specifically, a deposition gas whose dew point is -80° C. or lower, preferably -100° C. or lower is used.

By increasing the substrate heating temperature during the deposition, migration of a sputtered particle is likely to occur after the sputtered particle is attached to a substrate surface. Specifically, the substrate heating temperature during the deposition is higher than or equal to 100° C. and lower than or equal to 740° C., preferably higher than or equal to 200° C. and lower than or equal to 500° C. By increasing the substrate heating temperature during the deposition, when the flat-plate-like sputtered particle reaches the substrate, migration occurs on the substrate surface, so that a flat plane of the flat-plate-like sputtered particle is attached to the substrate.

Furthermore, it is preferable that the proportion of oxygen in the deposition gas be increased and the power be optimized in order to reduce plasma damage at the deposition. The proportion of oxygen in the deposition gas is 30 vol % or higher, preferably 100 vol %.

As an example of the sputtering target, an In—Ga—Zn-based oxide target is described below.

The polycrystalline In—Ga—Zn-based oxide target is made by mixing InO_X powder, GaO_Y powder, and ZnO_Z powder in a predetermined ratio and performing heat treatment at a temperature higher than or equal to 1000° C. and lower than or equal to 1500° C. Note that X, Y, and Z are each a given positive number. Here, the predetermined molar ratio of InO_X powder to GaO_Y powder and ZnO_Z powder is, for example, 2:2:1, 5:1:5, 8:4:3, 3:1:1, 1:1:1, 4:2:3, or 3:1:2. The kinds of powder and the molar ratio for mixing powder may be determined as appropriate depending on the desired sputtering target.

With the use of the CAAC-OS film in a transistor, change in electrical characteristics of the transistor due to irradiation with visible light or ultraviolet light is small. Thus, the transistor has high reliability.

In the case where a CAAC-OS film is used for the first, second, and third oxide semiconductor layers, since the first oxide semiconductor layer has the same crystal structure as the second oxide semiconductor layer, the number of levels can be small at the interface thereof, so that high field-effect mobility can be achieved. Further, it is preferable that the second oxide semiconductor layer be formed on and in contact with the first oxide semiconductor layer that is a CAAC-OS film because the second oxide semiconductor layer formed over the first oxide semiconductor layer is easily crystallized using the first oxide semiconductor layer as a crystal seed, so that the first and second oxide semiconductor layers can have the same crystal structure.

A transistor structure with high field-effect mobility can be achieved.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A to 1D are cross-sectional views, a band diagram, and a top view illustrating one embodiment of the present invention.

FIGS. 2A to 2D are cross-sectional views illustrating manufacturing steps of one embodiment of the present invention.

FIGS. 15A to 15C illustrate electronic devices.

FIG. 16A is a schematic view of a flat-plate-like sputtered particle, FIG. 16B is a model diagram during deposition, and FIG. 16C is a model diagram showing the state of the flat-plate-like sputtered particle.

FIG. 17A is a model diagram during deposition and FIG. 17B is a model diagram showing the state where oxygen of a flat-plate-like sputtered particle is released.

FIGS. 18A and 18B are model diagrams during deposition, and FIG. 18C is a model diagram showing the state of the flat-plate-like sputtered particle.

DETAILED DESCRIPTION OF THE INVENTION

Hereinafter, embodiments of the present invention are described in detail with reference to the accompanying drawings. However, the present invention is not limited to the description below, and it is easily understood by those skilled in the art that modes and details disclosed herein can be modified in various ways. Therefore, the present invention is not construed as being limited to description of the embodiments.

(Embodiment 1)

In this embodiment, one embodiment of a semiconductor device is described with reference to FIGS. 1A to 1D. In this embodiment, a structural example of a transistor including an oxide semiconductor film is described.

Note that the cross-sectional view of a transistor **418** in FIG. 1A corresponds to a structural view taken along a chain line A1-A2 in a top view in FIG. 1C. The cross-sectional view of the transistor **418** in FIG. 1D corresponds to a structural view taken along a chain line A2-A3 in a top view in FIG. 1C.

The transistor **418** illustrated in FIGS. 1A to 1D includes a base insulating layer having a two-layer structure over a substrate **400**, three oxide semiconductor layers which are over the base insulating layer and include at least a channel formation region, electrode layers **445a** and **445b** which are on and in contact with the oxide semiconductor layers, a gate electrode layer **401** over the electrode layers **445a** and **445b** and a gate insulating layer **402** having a two-layer structure, and the insulating layer **407** over the stack of oxide semiconductor layers, the gate insulating layer **402** having a two-layer structure, and the gate electrode layer **401**. The electrode layers **445a** and **445b** function as a source electrode layer and a drain electrode layer.

Although there is no particular limitation on a substrate which can be used as the substrate **400**, it is at least necessary that the substrate have heat resistance sufficient to withstand heat treatment performed later. A single crystal semiconductor substrate or a polycrystalline semiconductor substrate of silicon, silicon carbide, or the like or a compound semiconductor substrate of silicon germanium or the like may be used

as the substrate **400**. Alternatively, an SOI substrate, a substrate over which a semiconductor element is provided, or the like can be used. Further alternatively, a glass substrate of barium borosilicate glass, aluminoborosilicate glass, or the like, a ceramic substrate, a quartz substrate, or a sapphire substrate can be used.

For the first layer of the base insulating layer having a two-layer structure, a nitride insulating film **433** is formed, and for the second layer of the base insulating layer, an oxide insulating film **435** is formed. For the first layer of the gate insulating layer **402** having a two-layer structure, an oxide insulating film formed using a sputtering method, a molecular beam epitaxy (MBE) method, a chemical vapor deposition (CVD) method, a pulsed laser deposition (PLD) method, an atomic layer deposition (ALD) method, or the like, as appropriate is used. For the second layer of the gate insulating layer **402**, a nitride insulating film is used. As the oxide insulating layer, silicon oxide, gallium oxide, aluminum oxide, silicon oxynitride, silicon nitride oxide, hafnium oxide, tantalum oxide, or the like can be used. Further, for the nitride insulating film, an insulating layer formed of silicon nitride, silicon oxynitride, silicon nitride oxide, or the like is preferably used.

Here, silicon oxynitride means the one that contains more oxygen than nitrogen and for example, silicon oxynitride includes at least oxygen, nitrogen, and silicon at concentrations ranging from greater than or equal to 50 atomic % and less than or equal to 70 atomic %, greater than or equal to 0.5 atomic % and less than or equal to 15 atomic %, and greater than or equal to 25 atomic % and less than or equal to 35 atomic %, respectively. In the case where a substrate provided with a semiconductor element is used, a silicon nitride film is preferably used as the nitride insulating film **433**, which is formed by a plasma CVD method with use of a mixed gas of silane (SiH₄) and nitrogen (N₂) as a supply gas. This silicon nitride film also functions as a barrier film, which has a function of preventing entry of hydrogen or a hydrogen compound into an oxide semiconductor layer formed later so as to improve the reliability of a semiconductor device. In the case where the silicon nitride film is formed by a plasma chemical vapor deposition (CVD) method with use of a mixed gas of silane (SiH₄), nitrogen (N₂), and ammonia (NH₃) as a supply gas, the amount of defects in the film can be reduced as compared with the case where the silicon nitride film is formed with use of a mixed gas of silane (SiH₄) and nitrogen (N₂) as a supply gas. When the thickness of the silicon nitride film formed with use of a mixed gas of silane (SiH₄), nitrogen (N₂), and ammonia (NH₃) as a supply gas is greater than or equal to 300 nm and less than or equal to 400 nm, the ESD resistance can be 300 V or higher. Therefore, when a stack in which a silicon nitride film which is deposited using a mixed gas of silane (SiH₄) and nitrogen (N₂) as a supply gas is stacked over the silicon nitride film which is deposited to a thickness greater than or equal to 300 nm and less than or equal to 400 nm using a mixed gas of silane (SiH₄), nitrogen (N₂), and ammonia (NH₃) is used as the nitride insulating film **433**, a barrier film having a high ESD resistance can be achieved.

The stack of oxide semiconductor layers is formed of the three oxide semiconductor layers, in which the first oxide semiconductor layer S1, the second oxide semiconductor layer S2, and the third oxide semiconductor layer S3 are sequentially stacked. The three oxide semiconductor layers may be films having a crystalline structure or films having an amorphous structure.

Of the three oxide semiconductor layers, the first oxide semiconductor layer has the smallest thickness. The three

oxide semiconductor layers each have a thickness greater than or equal to 5 nm and less than or equal to 40 nm.

For example, a 5-nm-thick In—Ga—Zn-based oxide film which is deposited using a sputtering target having an atomic ratio of In:Ga:Zn=1:3:2 may be used as the first oxide semiconductor layer S1, a 10-nm-thick In—Ga—Zn-based oxide film which is deposited using a sputtering target having an atomic ratio of In:Ga:Zn=3:1:2 may be used as the second oxide semiconductor layer S2, and a 10-nm-thick In—Ga—Zn-based oxide film which is deposited using a sputtering target having an atomic ratio of In:Ga:Zn=1:1:1 may be used as the third oxide semiconductor layer S3. In the case of forming these three layers, each layer is preferably deposited by a sputtering method in a mixed atmosphere containing more oxygen than a rare gas, preferably in an oxygen atmosphere (oxygen: 100%), and all of the resulting oxide semiconductor layers can also be referred to as I-type oxide semiconductor layers.

The deposition condition may be changed successively during the deposition of each oxide semiconductor layer, so that an energy band diagram shown in FIG. 1B may be obtained. Alternatively, the constituent elements of each oxide semiconductor layer may be diffused interactively by heat treatment or the like, so that an energy band diagram shown in FIG. 1B may be obtained. The energy band diagram in FIG. 1B is an energy band which corresponds to a portion between C and C' in FIG. 1A.

It is further preferable that a first gate insulating layer **402a** in contact with the stack of oxide semiconductor layers include a region which contains oxygen in a proportion higher than that of oxygen in the stoichiometric composition (i.e., an oxygen-excess region). This is because, when the first gate insulating layer **402a** in contact with the stack of oxide semiconductor layers includes an oxygen-excess region, oxygen can be supplied to the stack of oxide semiconductor layers, elimination of oxygen from the stack of oxide semiconductor layers can be prevented, and oxygen vacancies can be reduced. In order to provide the oxygen-excess region in the first gate insulating layer **402a**, the first gate insulating layer **402a** is formed in an oxygen atmosphere, for example. Alternatively, oxygen may be introduced into the formed first gate insulating layer **402a** to provide the oxygen-excess region.

A second gate insulating layer **402b** is preferably formed using a silicon nitride film which is deposited by a plasma CVD method in which a mixed gas of silane (SiH₄) and nitrogen (N₂) is supplied. This silicon nitride film functions as a barrier film, which has a function of preventing entry of hydrogen or a hydrogen compound into the oxide semiconductor layers so as to improve the reliability of the transistor **418**.

Further, the gate insulating layer **402** does not have to be a stacked layer. For example, a 20-nm-thick silicon oxide film formed by a plasma CVD method may be used for the gate insulating layer **402**. In this case, after the silicon oxide film is formed, radical oxidation treatment using microwave plasma for reducing oxygen vacancies is preferably performed. For the conditions of the treatment, for example, a high-density plasma apparatus is used, a power of 3800 W is supplied with a power supply of 2.45 GHz, the pressure is 106.67 Pa, the substrate temperature is 325° C., the flow rate of argon is 900 sccm, and the flow rate of oxygen is 5 sccm. Here, a high-density plasma apparatus refers to an apparatus which can realize a plasma density higher than or equal to 1×10¹¹/cm³. For example, plasma is generated by applying a microwave power of 3 kW to 6 kW inclusive. By supplying the microwave power, the efficiency of decomposition of a source gas in the plasma is increased, so that oxygen radicals are

11

increased, whereby the source gas is oxidized. Thus, the oxygen content in the gate insulating layer **402** is in excess of that in the stoichiometric composition. Thus, it is possible to form an oxide insulating film which contains oxygen at a higher proportion than the stoichiometric composition. Further, before the gate insulating layer **402** is formed, plasma treatment in which a high-density plasma apparatus is used and nitrous oxide (N_2O) and a rare gas are introduced may be performed. In the case where a single layer of silicon oxide is used as the gate insulating layer **402**, the insulating layer **407** serves as a barrier film, so that reliability can be secured. (Embodiment 2)

In this embodiment, one embodiment of a semiconductor device and one embodiment of a method for manufacturing the semiconductor device are described with reference to FIGS. 2A to 2D and FIGS. 3A and 3B. In this embodiment, an example of a method for manufacturing a transistor including an oxide semiconductor film is described.

First, a nitride insulating film **433** is formed over a substrate **400** having an insulating surface and a conductive film is formed thereover by a sputtering method, an evaporation method, or the like. The conductive film is etched so that a conductive layer **491** and wiring layers **434** and **436** are formed.

There is no particular limitation on a substrate that can be used as the substrate **400** having an insulating surface as long as it has heat resistance enough to withstand heat treatment performed later. For example, a glass substrate of barium borosilicate glass, aluminoborosilicate glass, or the like, a ceramic substrate, a quartz substrate, or a sapphire substrate can be used. A single crystal semiconductor substrate or a polycrystalline semiconductor substrate of silicon, silicon carbide, or the like; a compound semiconductor substrate of silicon germanium or the like; an SOI substrate; or the like can be used as the substrate **400**, or the substrate provided with a semiconductor element can be used as the substrate **400**.

The nitride insulating film **433** can be formed using a single insulating film or a stack of insulating films selected from the following: a nitride insulating film of silicon nitride, aluminum nitride, or the like; an oxynitride insulating film of silicon oxynitride, aluminum oxynitride, or the like; or a nitride oxide insulating film of silicon nitride oxide or the like.

The conductive layer **491** and the wiring layers **434** and **436** can be formed using a metal material such as molybdenum, titanium, tantalum, tungsten, aluminum, copper, chromium, neodymium, or scandium or an alloy material which contains any of these materials as its main component. Alternatively, a semiconductor film typified by a polycrystalline silicon film doped with an impurity element such as phosphorus, or a silicide film such as a nickel silicide film may be used as the conductive layer **491**. The conductive layer **491** may have a single-layer structure or a stacked-layer structure.

The conductive layer **491** and the wiring layers **434** and **436** can also be formed using a conductive material such as indium oxide-tin oxide, indium oxide containing tungsten oxide, indium zinc oxide containing tungsten oxide, indium oxide containing titanium oxide, indium tin oxide containing titanium oxide, indium oxide-zinc oxide, or indium tin oxide to which silicon oxide is added. It is also possible that the conductive layer **491** and the wiring layers **434** and **436** have a stacked structure of the above conductive material and the above metal material.

In order to obtain a normally-off switching element, it is preferable that the threshold voltage of the transistor be made positive by using a material having a work function of 5 eV (electron volts) or higher, preferably 5.5 eV or higher, for a

12

gate electrode layer. Specifically, a material which includes an In—N bond and has a specific resistivity of $1 \times 10^{-1} \Omega \cdot \text{cm}$ to $1 \times 10^{-4} \Omega \cdot \text{cm}$, preferably $5 \times 10^{-2} \Omega \cdot \text{cm}$ to $1 \times 10^{-4} \Omega \cdot \text{cm}$, is used for the gate electrode layer. Examples of the material are an In—Ga—Zn-based oxide film containing nitrogen, an In—Sn—O film containing nitrogen, an In—Ga—O film containing nitrogen, an In—Zn—O film containing nitrogen, an In—O film containing nitrogen, and a metal nitride film (e.g., an InN film).

Next, an oxide insulating film is formed over the conductive layer **491** and the wiring layers **434** and **436**. The oxide insulating film has a projecting portion reflecting the shape of the conductive layer **491** on its surface.

The oxide insulating film can be formed by a plasma CVD method, a sputtering method, or the like using any of silicon oxide, silicon oxynitride, aluminum oxide, aluminum oxynitride, hafnium oxide, gallium oxide, gallium oxide zinc, and zinc oxide, or a mixed material thereof. The oxide insulating film may have either a single-layer structure or a stacked-layer structure.

Then, polishing treatment (e.g., chemical mechanical polishing (CMP)) is performed, whereby an oxide insulating film **435** which is planarized is formed and top surfaces of the wiring layers **434** and **436** and a top surface of the conductive layer **491** are exposed. After the CMP treatment, cleaning is performed and heat treatment for removing moisture attached on the substrate is performed. A cross-sectional view of a structure obtained after this step corresponds to FIG. 2A.

After the planarization, an insulating film **437** and a stack **403** of oxide semiconductor layers are formed. A cross-sectional view of a structure obtained after this step corresponds to FIG. 2B.

Then, patterning is performed using one mask and the insulating film **437** and the stack **403** of oxide semiconductor layers are selectively etched. A cross-sectional view of a structure obtained after this step corresponds to FIG. 2C. It is preferable that the insulating film **437** and the stack **403** of oxide semiconductor layers be formed successively without being exposed to the air because interfaces of the films can be prevented from being contaminated by an impurity.

The insulating film **437** is formed by a plasma CVD method or a sputtering method. In the case where a plasma CVD method is used, it is particularly preferable to use a plasma CVD method (also referred to as a microwave plasma CVD method) in which plasma is generated utilizing electric-field energy of a microwave and a source gas for the gate insulating film is excited by the plasma, and the excited source gas is reacted on a surface of an object to deposit a reactant. The insulating film formed by a plasma CVD method using a microwave is a dense film, and therefore, the insulating film **437** obtained by processing the insulating film is also a dense film. The insulating film **437** has a thickness greater than or equal to 5 nm and less than or equal to 300 nm.

The insulating film **437** can be formed using a single layer or a stack of layers selected from the following films: an oxide insulating film of silicon oxide, gallium oxide, hafnium oxide, yttrium oxide, aluminum oxide, or the like; an oxynitride insulating film of silicon oxynitride, aluminum oxynitride, or the like; or a nitride oxide insulating film of silicon nitride oxide or the like.

In this embodiment, the stack **403** of oxide semiconductor layers has a three-layer structure in which a first oxide semiconductor layer **403a**, a second oxide semiconductor layer **403b**, and a third oxide semiconductor layer **403c** are stacked in this order, as illustrated in FIG. 2C.

In this embodiment, as the first oxide semiconductor layer **403a**, an In—Ga—Zn-based oxide film which is deposited

13

using a sputtering target having an atomic ratio of In:Ga:Zn=1:3:2 and has a thickness greater than or equal to 5 nm and less than or equal to 10 nm is used.

As the second oxide semiconductor layer **403b**, an In—Ga—Zn-based oxide film is deposited to a thickness greater than or equal to 10 nm and less than or equal to 30 nm by a sputtering method using a sputtering target having an atomic ratio of In:Ga:Zn=3:1:2 in a mixed atmosphere containing oxygen and a rare gas or an oxygen atmosphere. Further, it is preferable that the second oxide semiconductor layer **403b** be a CAAC-OS film.

As the third oxide semiconductor layer **403c**, an In—Ga—Zn-based oxide semiconductor film is deposited to a thickness greater than or equal to 10 nm and less than or equal to 30 nm by a sputtering method using a sputtering target having an atomic ratio of In:Ga:Zn=1:1:1 in a mixed atmosphere containing oxygen and a rare gas or an oxygen atmosphere. Further, the third oxide semiconductor layer **403c** may have an amorphous structure but is preferably a CAAC-OS film.

With such a stacked-layer structure, a structure in which the second oxide semiconductor layer **403b** through which carriers flow is not in contact with the insulating film containing silicon is obtained.

When the insulating film **437** and the first oxide semiconductor layer **403a** are deposited successively without being exposed to the air, impurity contamination of an interface between the insulating film **437** and the first oxide semiconductor layer **403a** can be prevented. When the second oxide semiconductor layer **403b** and the third oxide semiconductor layer **403c** are deposited successively without being exposed to the air, impurity contamination of an interface between the second oxide semiconductor layer **403b** and the third oxide semiconductor layer **403c** can be prevented. The third oxide semiconductor layer **403c** also functions as a protective film that protects the second oxide semiconductor layer **403b** from exposure to the air in etching or the like in a later step.

In the case where the first oxide semiconductor layer **403a**, the second oxide semiconductor layer **403b**, and the third oxide semiconductor layer **403c** are stacked successively without being exposed to the air, a multi-chamber deposition apparatus in which a plurality of sputtering apparatuses is provided may be used.

In order that the second oxide semiconductor layer **403b** through which carriers flow is not in contact with the insulating film containing silicon, top and bottom interfaces of the second oxide semiconductor layer **403b** are protected with the first oxide semiconductor layer **403a** and third oxide semiconductor layer **403c** so that an impurity such as silicon does not enter the second oxide semiconductor layer **403b** and the interfaces thereof; accordingly, high field-effect mobility is achieved.

After the insulating film **437** and the stack **403** of oxide semiconductor layers are formed, a conductive film is formed. This conductive film is selectively etched, so that the electrode layers **445a** and **445b** and a conductive layer **442** are formed. A cross-sectional view of a structure obtained after this step corresponds to FIG. 2D. By performing etching plural times at this time, electrodes which have projecting regions in their bottom edge portions when seen in cross-section are formed. The electrode layers **445a** and **445b** having the projecting regions in the bottom edge portions function as a source electrode layer and a drain electrode layer of the transistor. The electrode layer **445a** is provided on and in contact with the wiring layer **436** and the electrode layer **445b** is provided on and in contact with the wiring layer **434**.

A distance between the electrode layers **445a** and **445b** corresponds to a channel length *L* of the transistor. In order

14

that the channel length *L* of the transistor is less than 50 nm, for example, approximately 20 nm, it is preferable that a resist be subjected to light exposure using an electron beam and the developed mask be preferably used as an etching mask of the conductive film. At a higher acceleration voltage, an electron beam can provide a finer pattern. The use of multiple electron beams can shorten the process time per substrate. In an electron beam writing apparatus capable of electron beam irradiation, the acceleration voltage is preferably in the range from 5 kV to 50 kV, for example. The current intensity is preferably in the range from 5×10^{-12} A to 1×10^{-11} A. The minimum beam size is preferably 2 nm or less. The minimum possible pattern line width is preferably 8 nm or less. Under the above conditions, a pattern with a width of, for example, 30 nm or less, preferably 20 nm or less, more preferably 8 nm or less, can be obtained.

The gate insulating layer **402** is provided over the electrode layers **445a** and **445b** and the conductive layer **442** and also provided over the stack **403** of oxide semiconductor layers. A material of the gate insulating layer **402** can be a silicon oxide film, a gallium oxide film, a gallium oxide zinc film, a Ga_2O_3 (Gd_2O_3) film, a zinc oxide film, an aluminum oxide film, a silicon nitride film, a silicon oxynitride film, an aluminum oxynitride film, or a silicon nitride oxide film.

It is preferable that the gate insulating layer **402** include a region containing oxygen in a proportion higher than that of the stoichiometric composition (an oxygen-excess region). This is because, when an insulating layer in contact with the stack **403** of oxide semiconductor layers includes an oxygen-excess region, oxygen can be supplied to the stack **403** of oxide semiconductor layers, release of oxygen from the stack **403** of oxide semiconductor layers can be prevented, and oxygen vacancies can be reduced. In order to provide the oxygen-excess region in the gate insulating layer **402**, the gate insulating layer **402** is formed in an oxygen atmosphere, for example. Alternatively, oxygen may be introduced into the deposited gate insulating layer **402** to provide the oxygen-excess region therein. Further, as illustrated in FIG. 2D, the gate insulating layer **402** preferably has a stacked-layer structure of a first gate insulating layer **402a** and a second gate insulating layer **402b**. The stacked-layer structure is formed in such a manner that, over an insulating film including a region containing excess oxygen (oxygen-excess region), a silicon oxide film or a silicon oxynitride film is formed on a condition where a high frequency power higher than or equal to 0.17 W/cm^2 and lower than or equal to 0.5 W/cm^2 , preferably higher than or equal to 0.26 W/cm^2 and lower than or equal to 0.35 W/cm^2 , is supplied. Specifically, the silicon oxynitride film is formed in conditions where silane (SiH_4) and dinitrogen monoxide (N_2O) are supplied as source gases at 160 sccm and 4000 sccm, respectively; the pressure of a treatment chamber is adjusted to 200 Pa; and a power of 1500 W is supplied with a high-frequency power supply of 27.12 MHz. Further, the substrate temperature at which the silicon oxynitride film is formed is set to 220° C.

Next, the gate insulating layer **402** is selectively etched to form an opening reaching the conductive layer **442**. After that, a conductive film is formed and selectively etched, whereby an electrode layer **438** which is electrically connected to the conductive layer **442** is formed and a gate electrode layer **401** is formed over the stack **403** of oxide semiconductor layers with the gate insulating layer **402** positioned therebetween. Then, an insulating layer **407** functioning as a barrier film is provided to cover the gate electrode layer **401** and the electrode layer **438**.

As the insulating layer **407**, it is preferable to use a silicon nitride film which is deposited by a plasma CVD method in

15

which a mixed gas of silane (SiH_4) and nitrogen (N_2) is supplied. This silicon nitride film functions as a barrier film and prevents hydrogen or a hydrogen compound from entering an oxide semiconductor layer to be formed later, thereby improving the reliability of the semiconductor device.

The gate electrode layer **401** and the electrode layer **438** can be formed using a metal material such as molybdenum, titanium, tantalum, tungsten, aluminum, copper, chromium, neodymium, or scandium or an alloy material which contains any of these materials as its main component. A semiconductor film which is doped with an impurity element such as phosphorus and is typified by a polycrystalline silicon film, or a silicide film of nickel silicide or the like can also be used as the gate electrode layer **401**. The gate electrode layer **401** and the electrode layer **438** each have either a single-layer structure or a stacked-layer structure.

In this embodiment, a tungsten film is used as the gate electrode layer **401** on and in contact with the gate insulating layer **402**.

Through the above process, a transistor **415** of this embodiment can be manufactured (see FIG. **3A**). The transistor **415** is an example of a dual-gate transistor. FIG. **3A** is a cross-sectional view of the transistor **415** in the channel length direction. In the dual-gate transistor **415**, the insulating film **437** also serves as a gate insulating film.

The conductive layer **491** can function as a second gate electrode layer (also referred to as back gate) for controlling the electrical characteristics of the transistor **415**. For example, by setting the potential of the conductive layer **491** to GND (or a fixed potential), the threshold voltage of the transistor **415** is increased, so that the transistor **415** can be normally off.

FIG. **3B** is an example of a top view of the transistor **415**. FIG. **3A** is a cross section taken along a chain line X-Y in FIG. **3B**.

This embodiment can be freely combined with Embodiment 1. (Embodiment 3)

In this embodiment, a structural example in FIG. **4A** which is partly different from the structure of FIG. **1A** and a manufacturing method thereof are described below.

First, over the substrate **400**, the oxide insulating film **435** is formed. The oxide insulating film **435** can be formed by a plasma CVD method, a sputtering method, or the like, using silicon oxide, silicon oxynitride, aluminum oxide, aluminum oxynitride, hafnium oxide, gallium oxide, gallium zinc oxide, zinc oxide, or a mixed material of any of these materials. The oxide insulating film may have either a single-layer structure or a stacked-layer structure. If needed, a nitride insulating film such as a silicon nitride film may be provided between the substrate **400** and the oxide insulating film **435**.

Next, the first oxide semiconductor layer **403a** and the second oxide semiconductor layer **403b** are formed by patterning using the same mask, and then the third oxide semiconductor layer **403c** is formed. In order to reduce oxygen vacancies in the second oxide semiconductor layer **403b**, the third oxide semiconductor layer **403c** may be formed after heat treatment in an oxygen atmosphere. The third oxide semiconductor layer **403c** is formed using a different mask from the first and second oxide semiconductor layers **403a** and **403b**, so that the third oxide semiconductor layer **403c** can cover the side surface of the first oxide semiconductor layer **403a** and the side and top surfaces of the second oxide semiconductor layer **403b** as illustrated in FIG. **4A**.

During etching of the first and second oxide semiconductor layers **403a** and **403b**, the thickness of a region of the oxide

16

insulating film **435** which is not covered with a mask becomes smaller as illustrated in FIG. **4A**.

Subsequently, a conductive film is formed. This conductive film is selectively etched, so that the electrode layers **445a** and **445b** are formed.

Then, the gate insulating layer **402** is provided over the electrode layers **445a** and **445b**, and is also provided over the third oxide semiconductor layer **403c**. As illustrated in FIG. **4B**, since the side surface of the second oxide semiconductor layer **403b** is covered with the third oxide semiconductor layer **403c**, the side surface of the second oxide semiconductor layer **403b** is not in contact with the gate insulating layer **402**.

Next, a conductive film is formed over the gate insulating layer **402** and selectively etched to form the gate electrode layer **401** over the third oxide semiconductor layer **403c** with the gate insulating layer **402** positioned therebetween. The insulating layer **407** functioning as a barrier film is provided so as to cover the gate electrode layer **401**.

Through the above process, a transistor **416** illustrated in FIG. **4A** can be manufactured. FIG. **4C** is a top view. A cross section taken along a chain line B1-B2 in FIG. **4C** corresponds to FIG. **4A** and a cross section taken along a dotted line B2-B3 in FIG. **4C** corresponds to FIG. **4B**. As illustrated in FIG. **4C**, the periphery of the third oxide semiconductor layer **403c** is positioned outside the periphery of the second oxide semiconductor layer **403b**.

This embodiment can be freely combined with Embodiment 1. Portions denoted by the same reference numerals as those of the drawings used in Embodiment 1 can be formed using the same material as those of Embodiment 1. Instead of the stack **403** of oxide semiconductor layers described in Embodiment 1, a structure in which the third oxide semiconductor layer **403c** covers the side surface of the first oxide semiconductor layer **403a** and the side and top surfaces of the second oxide semiconductor layer **403b** may be employed. Since the third oxide semiconductor layer **403c** can be provided between the second oxide semiconductor layer **403b** and the electrode layer **445a**, leakage current can be reduced. (Embodiment 4)

In this embodiment, an example of a semiconductor device including the transistor described in Embodiment 2 is described with reference to FIGS. **5A** and **5B**.

The semiconductor device illustrated in FIGS. **5A** and **5B** includes transistors **740** and **750** including a first semiconductor material in a lower portion, and a transistor **610** including a second semiconductor material in an upper portion. The transistor **610** has a similar structure to the transistor **415** described in Embodiment 2. The same reference numerals are used for the same parts as those in FIGS. **3A** and **3B**. FIG. **5B** is a circuit diagram of the semiconductor device in FIG. **5A**.

Here, the first semiconductor material and the second semiconductor material are preferably materials having different band gaps. For example, the first semiconductor material may be a semiconductor material other than an oxide semiconductor (e.g., silicon) and the second semiconductor material may be an oxide semiconductor. A transistor including a material such as silicon can operate at high speed easily. On the other hand, a transistor including an oxide semiconductor enables charge to be held for a long time owing to its characteristics.

As a substrate used in the semiconductor device, a single crystal semiconductor substrate or a polycrystalline semiconductor substrate made of silicon or silicon carbide, a compound semiconductor substrate made of silicon germanium or the like, a silicon on insulator (SOI) substrate, or the like can be used. A channel formation region of the transistor can be formed in or over the semiconductor substrate. The semi-

17

conductor device in FIG. 5A is an example in which the channel formation region is formed in the semiconductor substrate to form a lower transistor.

In the semiconductor device in FIG. 5A, a single crystal silicon substrate is used as a substrate 700, the transistors 740 and 750 are formed using the single crystal silicon substrate, and single crystal silicon is used as the first semiconductor material. The transistor 740 is an n-channel transistor and the transistor 750 is a p-channel transistor. The transistor 740 and the transistor 750 which are electrically connected to each other form a complementary metal oxide semiconductor (CMOS) circuit 760.

In this embodiment, the single crystal silicon substrate imparting p-type conductivity is used as the substrate 700; thus, an n-well is formed by adding an impurity element imparting n-type conductivity to a region in which the p-channel transistor 750 is to be formed. A channel formation region 753 of the transistor 750 is formed in the n-well. As the impurity element imparting n-type conductivity, phosphorus (P), arsenic (As), or the like can be used.

Therefore, an impurity element imparting p-type conductivity is not added to a formation region of the transistor 740 that is the n-channel transistor; however, a p-well may be formed by adding an impurity element imparting p-type conductivity. As the impurity element imparting p-type conductivity, boron (B), aluminum (Al), gallium (Ga), or the like can be used.

Meanwhile, when a single-crystal silicon substrate imparting n-type conductivity is used, an impurity element imparting p-type conductivity may be added to form a p-well.

The transistor 740 includes a channel formation region 743, an n-type impurity region 744 functioning as a lightly doped drain (LDD) region or an extension region, an n-type impurity region 745 functioning as a source region or a drain region, a gate insulating film 742, and a gate electrode layer 741. The n-type impurity region 745 has a higher impurity concentration than the n-type impurity region 744. The side surface of the gate electrode layer 741 is provided with a sidewall insulating layer 746. With the use of the gate electrode layer 741 and the sidewall insulating layer 746 as masks, the n-type impurity region 744 and the n-type impurity region 745 which have different impurity concentrations can be formed in a self-aligned manner.

The transistor 750 includes the channel formation region 753, a p-type impurity region 754 functioning as a lightly doped drain (LDD) region or an extension region, a p-type impurity region 755 functioning as a source region or a drain region, a gate insulating film 752, and a gate electrode layer 751. The p-type impurity region 755 has a higher impurity concentration than the p-type impurity region 754. The side surface of the gate electrode layer 751 is provided with a sidewall insulating layer 756. With the use of the gate electrode layer 751 and the sidewall insulating layer 756 as masks, the p-type impurity region 754 and the p-type impurity region 755 which have different impurity concentrations can be formed in a self-aligned manner.

In the substrate 700, the transistor 740 and the transistor 750 are isolated from each other by an element isolation region 789. An insulating film 788 and an insulating film 687 are stacked over the transistor 740 and the transistor 750. A wiring layer 647 in contact with the n-type impurity region 745 through an opening in the insulating film 788 and the insulating film 687 and a wiring layer 657 in contact with the p-type impurity region 755 through an opening in the insulating film 788 and the insulating film 687 are provided over the insulating film 687. A wiring layer 748 is provided over the insulating film 687 so as to electrically connect the tran-

18

sistor 740 and the transistor 750. The wiring layer 748 is electrically connected to the n-type impurity region 745 through an opening in the insulating film 788 and the insulating film 687 and reaching the n-type impurity region 745. Further, the wiring layer 748 is electrically connected to the p-type impurity region 755 through an opening in the insulating film 788 and the insulating film 687 and reaching the p-type impurity region 755.

An insulating film 686 is provided over the insulating film 687, the wiring layer 647, the wiring layer 748, and the wiring layer 657. A wiring layer 658 is formed over the insulating film 686. The wiring layer 658 is electrically connected to a gate wiring through an opening in the insulating films 788, 687, and 686. The gate wiring is formed over the gate insulating film 742 and the gate insulating film 752. The gate wiring branches into the gate electrode layer 741 and the gate electrode layer 751.

The semiconductor device of this embodiment is not limited to the structure in FIG. 5A. As the transistors 740 and 750, a transistor containing silicide (salicide) or a transistor which does not include a sidewall insulating layer may be used. When a structure that contains silicide (salicide) is used, the resistance of the source region and the drain region can be further lowered and the operation speed of the semiconductor device is increased. Further, the semiconductor device can be operated at low voltage, so that power consumption of the semiconductor device can be reduced.

Next, the structures of upper elements provided over the lower transistor in the semiconductor device in FIGS. 5A and 5B are described.

An insulating film 684 is stacked over the insulating film 686 and the wiring layer 658. The conductive layer 491 and a wiring layer 692 are formed over the insulating film 684.

The oxide insulating film 435 is provided over the conductive layer 491 and the wiring layer 692. The insulating film 437 is provided over the oxide insulating film 435. The first oxide semiconductor layer 403a is provided over the insulating film 437. The second oxide semiconductor layer 403b and the third oxide semiconductor layer 403c which each have a different composition from the first oxide semiconductor layer 403a are provided over the first oxide semiconductor layer 403a. Further, the electrode layers 445a and 445b which have projecting regions in the bottom edge portions are provided over the third oxide semiconductor layer 403c. The gate insulating layer 402 is provided on and in contact with a region of the second oxide semiconductor layer 403b which does not overlap with the electrode layer 445a or the electrode layer 445b (the channel formation region), and the gate electrode layer 401 is provided thereover.

A capacitor 690 is provided over the same oxide insulating film 435 as the transistor 610 without an increase in the number of steps. In the capacitor 690, the electrode layer 445a serves as one electrode, a capacitor electrode layer 693 serves as the other electrode, and the gate insulating layer 402 provided therebetween serves as a dielectric. The capacitor electrode layer 693 is formed in the same step as the gate electrode layer 401.

By setting the potential of the conductive layer 491 to GND (or a fixed potential), the conductive layer 491 serves as a back gate which controls the electrical characteristics of the transistor 610. The conductive layer 491 has a function of preventing static electricity. In the case where the threshold voltage of the transistor 610 is not required to be controlled by the conductive layer 491 in order to make the transistor 610 be a normally-off transistor, the conductive layer 491 is not necessarily provided. In the case where the transistor 610 is used for part of a particular circuit and a problem might be

19

caused by providing the conductive layer **491**, the conductive layer **491** is not necessarily provided in the circuit.

The wiring layer **692** is electrically connected to the wiring layer **658** through an opening in the insulating film **684**. In the example in this embodiment, the insulating film **684** is subjected to planarization treatment using a CMP method.

In the semiconductor device, the insulating film **684** is provided between the lower portion and the upper portion, and functions as a barrier film to prevent impurities such as hydrogen, which cause deterioration or a change in electrical characteristics of the transistor **610** in the upper portion, from entering the upper portion from the lower portion. Thus, a fine inorganic insulating film (e.g., an aluminum oxide film or a silicon nitride film) having a good property of blocking impurities or the like is preferably used as the insulating film **684**. The insulating film **684** can be formed by using the same material as the nitride insulating film **433** described in Embodiment 1.

In the case of using the same manufacturing method as that described in Embodiment 2, the transistor **610** can be manufactured similarly to the transistor **415**. After that insulating layer **407** is formed, an interlayer insulating film **485** is formed. Further, a semiconductor device having a multilayer structure in which an embedded wiring is formed in the interlayer insulating film **485** and another semiconductor element, another wiring, or the like is formed above the embedded wiring may be manufactured.

This embodiment can be freely combined with Embodiment 1, 2, or 3. (Embodiment 5)

As another example of a semiconductor device including the transistor described in Embodiment 2, a cross-sectional view of a NOR circuit, which is a logic circuit, is illustrated in FIG. 6A. FIG. 6B is a circuit diagram of the NOR circuit in FIG. 6A, and FIG. 6C is a circuit diagram of a NAND circuit.

In the NOR circuit illustrated in FIGS. 6A and 6B, p-channel transistors **801** and **802** each have a structure similar to that of the transistor **750** in FIGS. 5A and 5B in that a single crystal silicon substrate is used for a channel formation region, and n-channel transistors **803** and **804** each have a structure similar to that of the transistor **610** in FIGS. 5A and 5B and that of the transistor **415** in Embodiment 2 in that an oxide semiconductor film is used for a channel formation region.

In the NOR circuit illustrated in FIGS. 6A and 6B, a conductive layer **491** for controlling electrical characteristics of the transistors is provided to overlap with gate electrode layers with oxide semiconductor films provided therebetween in the transistors **803** and **804**. By controlling the potential of the conductive layer to GND, for example, the threshold voltages of the transistors **803** and **804** are increased, so that the transistors can be normally off. In the NOR circuit in this embodiment, conductive layers which are provided in the transistors **803** and **804** and can function as back gates are electrically connected to each other. However, the present invention is not limited to the structure, and the conductive layers functioning as back gates may be electrically controlled independently.

In the semiconductor device illustrated in FIG. 6A, a single crystal silicon substrate is used as a substrate **800**, the transistor **802** is formed using the single crystal silicon substrate, and the transistor **803** in which a stack of oxide semiconductor layers is used for a channel formation region is formed over the transistor **802**.

The gate electrode layer **401** of the transistor **803** is electrically connected to a wiring layer **832**. The wiring layer **832** is electrically connected to a wiring layer **835**. The gate electrode layer **401** of the transistor **803** is electrically connected

20

to an embedded wiring, and the embedded wiring is electrically connected to an electrode layer **842**. Note that the embedded wiring includes a first barrier metal film **486**, a second barrier metal film **488**, and a low-resistance conductive layer **487** surrounded by the first barrier metal film **486** and the second barrier metal film **488**.

The embedded wiring is formed in such a manner that a contact hole reaching the electrode layer **842** is formed in the interlayer insulating film **485**, the first barrier metal film **486** is formed, and a copper film or a copper alloy film is formed thereover so as to form the low-resistance conductive layer **487**. Then, polishing is performed for planarization, and the second barrier metal film **488** is formed so as to protect the exposed low-resistance conductive layer **487**. The embedded wiring includes the first barrier metal film **486**, the second barrier metal film **488**, and the low-resistance conductive layer **487** surrounded by the first barrier metal film **486** and the second barrier metal film **488**.

Each of the first barrier metal film **486** and the second barrier metal film **488** may be formed using a conductive material which suppresses diffusion of copper contained in the low-resistance conductive layer **487**. Examples of the conductive material are a tantalum nitride film, a molybdenum nitride film, and a tungsten nitride film.

The wiring layer **832** is provided in an opening formed in an insulating film **826** and an insulating film **830**. The wiring layer **835** is provided in an opening formed in an insulating film **833**. The electrode layer **842** is formed over the wiring layer **835**.

An electrode layer **825** of the transistor **802** is electrically connected to the electrode layer **445b** of the transistor **803** through wiring layers **831** and **834**. The wiring layer **831** is formed in an opening in the insulating film **830**, and the wiring layer **834** is formed in an opening in the insulating film **833**. The electrode layer **445a** and the electrode layer **445b** function as source and drain electrode layers of the transistor **803**.

The first oxide semiconductor layer **403a** is formed on and in contact with the insulating film **437**. The third oxide semiconductor layer **403c** is formed on and in contact with the second oxide semiconductor layer **403b**. With the insulating film **437** and the gate insulating layer **402**, unnecessary release of oxygen can be suppressed, and the second oxide semiconductor layer **403b** can be kept in an oxygen excess state. Thus, in the transistor **803**, oxygen vacancies in the second oxide semiconductor layer **403b** and at the interface thereof can be filled efficiently. The transistor **804** has a structure and an effect which are similar to those of the transistor **803**.

In the NAND circuit in FIG. 6C, p-channel transistors **811** and **814** each have a structure similar to that of the transistor **750** in FIGS. 5A and 5B, and n-channel transistors **812** and **813** each have a structure similar to that of the transistor **610** in FIGS. 5A and 5B in that an oxide semiconductor film is used for a channel formation region.

In the NAND circuit illustrated in FIG. 6C, conductive layers controlling electrical characteristics of the transistors are provided to overlap with gate electrode layers with oxide semiconductor films provided therebetween in the transistors **812** and **813**. By controlling the potential of the conductive layer to GND, for example, the threshold voltages of the transistors **812** and **813** are increased, so that the transistors can be normally off. In the NAND circuit in this embodiment, the conductive layers which are provided in the transistors **812** and **813** and function as back gates are electrically connected to each other. However, the present invention is not

21

limited to the structure, and the conductive layers functioning as back gates may be electrically controlled independently.

By applying a transistor including an oxide semiconductor for a channel formation region and having extremely small off-state current to the semiconductor device in this embodiment, power consumption of the semiconductor device can be sufficiently reduced.

A semiconductor device which is miniaturized, is highly integrated, and has stable and excellent electrical characteristics by stacking semiconductor elements including different semiconductor materials and a method for manufacturing the semiconductor device can be provided.

The NOR circuit and the NAND circuit including the transistors described in Embodiment 2 are described as examples in this embodiment; however, the present invention is not limited to the circuits, and an AND circuit, an OR circuit, or the like can be formed using the transistors described in Embodiment 2 or 3. For example, a semiconductor device (storage device) in which stored data can be held even when power is not supplied and which has an unlimited number of times of writing with the transistors described in Embodiment 2 or 3 can be manufactured.

FIG. 7 is an example of a circuit diagram of a semiconductor device.

In FIG. 7, a first wiring (a 1st line) is electrically connected to a source electrode layer of a transistor 160. A second wiring (2nd line) is electrically connected to a drain electrode layer of the transistor 160. Any of the transistors 740, 750, and 802 described in this embodiment can be used as the transistor 160.

A third wiring (3rd line) is electrically connected to one of a source electrode layer and a drain electrode layer of a transistor 162, and a fourth wiring (4th line) is electrically connected to a gate electrode layer of the transistor 162. A gate electrode layer of the transistor 160 and the other of the source electrode and the drain electrode of the transistor 162 are electrically connected to one electrode of a capacitor 164. A fifth wiring (5th line) and the other electrode of the capacitor 164 are electrically connected to each other.

For the transistor 162, any of the structures of the transistors 415 and 416 described in Embodiment 2 or 3 can be used.

The semiconductor device having the circuit configuration in FIG. 7 utilizes a characteristic in which the potential of the gate electrode layer of the transistor 160 can be held, and thus enables data writing, holding, and reading as follows.

Writing and holding of data are described. First, the potential of the fourth wiring is set to a potential at which the transistor 162 is turned on, so that the transistor 162 is turned on. Accordingly, the potential of the third wiring is supplied to the gate electrode layer of the transistor 160 and to the capacitor 164. That is, predetermined charge is supplied to the gate electrode layer of the transistor 160 (writing). Here, charge for supply of a potential level or charge for supply of a different potential level (hereinafter referred to as a low-level charge and a high-level charge) is given. After that, the potential of the fourth wiring is set to a potential at which the transistor 162 is turned off, so that the transistor 162 is turned off. Thus, the charge given to the gate electrode layer of the transistor 160 is held (holding).

Since the off-state current of the transistor 162 is extremely small, the charge of the gate electrode layer of the transistor 160 is held for a long time.

Next, reading of data is described. By supplying an appropriate potential (a reading potential) to the fifth wiring while a predetermined potential (a constant potential) is supplied to the first wiring, the potential of the second wiring varies depending on the amount of charge held in the gate electrode

22

layer of the transistor 160. This is because in general, when the transistor 160 is an n-channel transistor, an apparent threshold voltage V_{th_H} in the case where the high-level charge is given to the gate electrode layer of the transistor 160 is lower than an apparent threshold voltage V_{th_L} in the case where the low-level charge is given to the gate electrode layer of the transistor 160. Here, an apparent threshold voltage refers to the potential of the fifth wiring, which is needed to turn on the transistor 160. Thus, the potential of the fifth wiring is set to a potential V_0 which is between V_{th_H} and V_{th_L} , whereby charge given to the gate electrode layer of the transistor 160 can be determined. For example, in the case where the high-level charge is given in writing, when the potential of the fifth wiring is set to $V_0 (>V_{th_H})$, the transistor 160 is turned on. In the case where a low-level charge is given in writing, even when the potential of the fifth wiring is set to $V_0 (<V_{th_L})$, the transistor 160 remains in an off state. Therefore, the stored data can be read by the potential of the second wiring.

Note that in the case where memory cells are arrayed to be used, only data of desired memory cells needs to be read. In the case where such reading is not performed, a potential at which the transistor 160 is turned off regardless of the state of the gate electrode layer of the transistor 160, that is, a potential smaller than V_{th_H} may be given to the fifth wiring. Alternatively, a potential at which the transistor 160 is turned on regardless of the state of the gate electrode layer, that is, a potential higher than V_{th_L} may be given to the fifth wiring.

FIG. 8 illustrates another example of one embodiment of the structure of the storage device.

FIG. 8 is a perspective view of a storage device. The storage device illustrated in FIG. 8 includes a plurality of layers of memory cell arrays (memory cell arrays 3400(1) to 3400(n) (n is an integer greater than or equal to 2)) each including a plurality of memory cells as memory circuits in the upper portion, and a logic circuit 3004 in the lower portion which is necessary for operating the memory cell arrays 3400(1) to 3400(n).

FIG. 8 illustrates the logic circuit 3004, the memory cell array 3400(1), and the memory cell array 3400(2), in which a memory cell 3170a and a memory cell 3170b are illustrated as typical examples among the plurality of memory cells included in the memory cell array 3400(1) and the memory cell array 3400(2). The memory cell 3170a and the memory cell 3170b can have a configuration similar to the circuit configuration described in this embodiment with reference to FIG. 7, for example.

A transistor in which a channel formation region is formed in an oxide semiconductor film is used as each transistor included in the memory cells 3170a and 3170b. The structure of the transistor in which the channel formation region is formed in the oxide semiconductor film is the same as the structure described in Embodiment 2; thus, the description of the structure is omitted.

The logic circuit 3004 includes a transistor in which a semiconductor material other than an oxide semiconductor is used as a channel formation region. For example, the transistor can be a transistor obtained in such a manner that an element isolation insulating layer is provided on a substrate including a semiconductor material (e.g., silicon) and a region serving as the channel formation region is formed in a region surrounded by the element isolation insulating layer. Note that the transistor may be a transistor obtained in such a manner that the channel formation region is formed in a semiconductor film such as a polycrystalline silicon film formed on an insulating surface or in a silicon film of an SOI substrate.

The memory cell arrays **3400(1)** to **3400(n)** and the logic circuit **3004** are stacked with interlayer insulating layers provided therebetween, and electrical connection or the like may be established as appropriate by an electrode or a wiring penetrating the interlayer insulating layers.

When a transistor having a channel formation region formed using an oxide semiconductor and having extremely small off-state current is applied to the semiconductor device in this embodiment, the semiconductor device can store data for an extremely long period. In other words, power consumption can be adequately reduced because refresh operation becomes unnecessary or the frequency of refresh operation can be extremely low. Moreover, stored data can be held for a long period even when power is not supplied (note that a potential is preferably fixed).

Further, in the semiconductor device described in this embodiment, high voltage is not needed for writing data and there is no problem of deterioration of elements. For example, unlike a conventional non-volatile memory, it is not necessary to inject and extract electrons into and from a floating gate; thus, the problem of deterioration of a gate insulating film does not occur. In other words, the semiconductor device according to one embodiment of the present invention does not have a limit on the number of times of writing which is a problem in a conventional nonvolatile memory, and reliability thereof is drastically improved. Furthermore, data is written depending on the on state and the off state of the transistor, whereby high-speed operation can be easily realized.

As described above, a miniaturized and highly-integrated semiconductor device having high electrical characteristics and a method for manufacturing the semiconductor device can be provided.

This embodiment can be freely combined with any of Embodiments 1, 2, 3 and 4. (Embodiment 6)

In this embodiment, a central processing unit (CPU) in which at least one of the transistors **415** and **416** described in Embodiment 2 or 3 is provided in part of the CPU is described as an example of a semiconductor device.

FIG. 9A is a block diagram illustrating a specific structure of a CPU. The CPU illustrated in FIG. 9A includes an arithmetic logic unit (ALU) **1191**, an ALU controller **1192**, an instruction decoder **1193**, an interrupt controller **1194**, a timing controller **1195**, a register **1196**, a register controller **1197**, a bus interface (Bus I/F) **1198**, a rewritable ROM **1199**, and a ROM interface (ROM I/F) **1189** over a substrate **1190**. A semiconductor substrate, an SOI substrate, a glass substrate, or the like is used as the substrate **1190**. The ROM **1199** and the ROM interface **1189** may each be provided over a separate chip. Obviously, the CPU illustrated in FIG. 9A is only an example in which the structure is simplified, and a variety of structures is applied to an actual CPU depending on the application.

An instruction that is input to the CPU through the bus interface **1198** is input to the instruction decoder **1193** and decoded therein, and then, input to the ALU controller **1192**, the interrupt controller **1194**, the register controller **1197**, and the timing controller **1195**.

The ALU controller **1192**, the interrupt controller **1194**, the register controller **1197**, and the timing controller **1195** conduct various controls in accordance with the decoded instruction. Specifically, the ALU controller **1192** generates signals for controlling the operation of the ALU **1191**. While the CPU is executing a program, the interrupt controller **1194** determines an interrupt request from an external input/output device or a peripheral circuit on the basis of its priority or a mask state, and processes the request. The register controller

1197 generates an address of the register **1196**, and reads/writes data from/to the register **1196** in accordance with the state of the CPU.

The timing controller **1195** generates signals for controlling operation timings of the ALU **1191**, the ALU controller **1192**, the instruction decoder **1193**, the interrupt controller **1194**, and the register controller **1197**. For example, the timing controller **1195** includes an internal clock generator for generating an internal clock signal CLK2 based on a reference clock signal CLK1, and supplies the internal clock signal CLK2 to the above circuits.

In the CPU illustrated in FIG. 9A, a memory cell is provided in the register **1196**. As the memory cell of the register **1196**, the memory cell described in Embodiment 5 can be used.

In the CPU illustrated in FIG. 9A, the register controller **1197** selects operation of holding data in the register **1196** in accordance with an instruction from the ALU **1191**. That is, the register controller **1197** selects whether data is held by a flip-flop or by a capacitor in the memory cell included in the register **1196**. When data holding by the flip-flop is selected, a power supply voltage is supplied to the memory cell in the register **1196**. When data holding by the capacitor is selected, the data is rewritten in the capacitor, and supply of power supply voltage to the memory cell in the register **1196** can be stopped.

The power supply can be stopped by a switching element provided between a memory cell group and a node to which a power supply potential VDD or a power supply potential VSS is supplied, as illustrated in FIG. 9B or FIG. 9C. Circuits illustrated in FIGS. 9B and 9C are described below.

FIGS. 9B and 9C each illustrate an example of a memory circuit in which one of the transistors **415**, and **416**, and **418** described in Embodiment 1, 2, or 3 is used as a switching element for controlling supply of power supply potential to memory cells.

The storage device illustrated in FIG. 9B includes a switching element **1141** and a memory cell group **1143** including a plurality of memory cells **1142**. Specifically, as each of the memory cells **1142**, the memory cell described in Embodiment 3 can be used. Each of the memory cells **1142** included in the memory cell group **1143** is supplied with the high-level power supply potential VDD via the switching element **1141**. Further, each of the memory cells **1142** included in the memory cell group **1143** is supplied with a potential of a signal IN and the low-level power supply potential VSS.

In FIG. 9B, any of the transistors **415**, **416**, and **418** described in Embodiment 1, 2, or 3 is used as the switching element **1141**, and the switching of the transistor is controlled by a signal SigA supplied to a gate electrode layer thereof.

Note that FIG. 9B illustrates a configuration in which the switching element **1141** includes only one transistor; however, one embodiment of the present invention is not limited thereto and the switching element **1141** may include a plurality of transistors. In the case where the switching element **1141** includes a plurality of transistors which serves as switching elements, the plurality of transistors may be connected to each other in parallel, in series, or in combination of parallel connection and series connection.

Although the switching element **1141** controls the supply of the high-level power supply potential VDD to each of the memory cells **1142** included in the memory cell group **1143** in FIG. 9B, the switching element **1141** may control the supply of the low-level power supply potential VSS.

FIG. 9C illustrates an example of a storage device in which each of the memory cells **1142** included in the memory cell group **1143** is supplied with the low-level power supply

25

potential VSS through the switching element **1141**. The supply of the low-level power supply potential VSS to each of the memory cells **1142** included in the memory cell group **1143** can be controlled by the switching element **1141**.

When a switching element is provided between a memory cell group and a node to which the power supply potential VDD or the power supply potential VSS is supplied, data can be held even in the case where an operation of a CPU is temporarily stopped and the supply of the power supply voltage is stopped; accordingly, power consumption can be reduced. Specifically, for example, while a user of a personal computer does not input data to an input device such as a keyboard, the operation of the CPU can be stopped, so that the power consumption can be reduced.

Although the CPU is given as an example in this embodiment, the transistor can also be applied to an LSI such as a digital signal processor (DSP), a custom LSI, or a field programmable gate array (FPGA).

The structures and methods described in this embodiment can be combined as appropriate with any of the structures and methods described in the other embodiments. (Embodiment 7)

In this embodiment, a display device including a bottom-gate transistor is described as an example. The bottom-gate transistor can be formed by a method partly different from the method for forming the transistor described in Embodiment 2; for example, an oxide insulating film is formed after a gate electrode layer is formed, the stack of oxide semiconductor layers is formed without CMP treatment, and a source electrode layer and a drain electrode layer are formed thereover. After the source electrode layer and the drain electrode layer are formed, wet etching using dilute hydrofluoric acid is performed so that part of the stack of oxide semiconductor layers is thinned; thus, a channel-etched transistor **310** illustrated in FIG. **10B** can be formed.

FIGS. **10A** to **10C** illustrate a structural example of the transistor **310**. FIG. **10A** is a plan view of the transistor **310**, FIG. **10B** is a cross-sectional view taken along the line X1-Y1 in FIG. **10A**, and FIG. **10C** is a cross-sectional view taken along the line V1-W1 in FIG. **10A**.

The transistor **310** in FIGS. **10A** to **10C** includes a gate electrode layer **401** provided over a substrate **400** having an insulating surface, a gate insulating layer **402** over the gate electrode layer **401**, a stack **403** of oxide semiconductor layers which is in contact with the gate insulating layer **402** and overlaps with the gate electrode layer **401**, and the electrode layer **445a** and the electrode layer **445b** which are electrically connected to the stack **403** of oxide semiconductor layers. Further, an insulating layer **407** which covers the electrode layer **445a** and the electrode layer **445b** and is in contact with the stack **403** of oxide semiconductor layers may be included as a component of the transistor **310**. The channel length of the transistor **310** can be, for example, 1 μm or more.

In this embodiment, the gate insulating layer **402** is a stack of a gate insulating layer **402a** which is in contact with the gate electrode layer **401** and a gate insulating layer **402b** which is provided over the gate insulating layer **402a** and is in contact with the stack **403** of oxide semiconductor layers. Further, the insulating layer **407** is a stack of an insulating layer **407a** which is in contact with the electrode layer **445a** and the electrode layer **445b** and an insulating layer **407b** which is over the insulating layer **407a**.

Materials, compositions, crystal structures, and the like of the first oxide semiconductor layer **403a** and the third oxide semiconductor layer **403c** are selected as appropriate so that the first oxide semiconductor layer **403a** and the third oxide semiconductor layer **403c** have the energy band diagram

26

shown in FIG. **1B**. When the oxide semiconductor layers have the same constituent elements, the first oxide semiconductor layer **403a** or the third oxide semiconductor layer **403c** may be formed to have a composition having a higher band gap.

The first oxide semiconductor layer **403a** prevents capture of carriers at the interface between the channel and the gate insulating layer, so that photodegradation (e.g., negative-bias temperature stress photodegradation) of the transistor can be reduced, which enables the transistor to have high reliability.

In general, an oxide semiconductor layer is mostly formed by a sputtering method. On the other hand, when the oxide semiconductor layer is formed by sputtering, in some cases, an ionized rare gas element (e.g., argon) or an element ejected from a surface of a sputtering target flicks off a constituent element of a film, such as a gate insulating layer, on which the oxide semiconductor layer is to be formed. The element flicked off from the film on which the oxide semiconductor layer is to be formed might enter the oxide semiconductor layer and function as an impurity element therein. In particular, a portion of the oxide semiconductor layer, which is in the vicinity of the surface on which the oxide semiconductor layer is formed, might have high concentration of the impurity element. Further, when the impurity element remains in the vicinity of the surface where the oxide semiconductor layer is to be formed, the resistance of the oxide semiconductor layer is increased, which causes the electrical characteristics of the transistor to be lowered.

However, in the transistor **310**, since the first oxide semiconductor layer **403a** is provided between the gate insulating layer **402** and the second oxide semiconductor layer **403b** in which the channel is formed, a constituent element of the gate insulating layer **402** can be prevented from diffusing to the channel. That is, the first oxide semiconductor layer **403a** may contain the constituent element (e.g., silicon) of the gate insulating layer **402** as an impurity. By including the first oxide semiconductor layer **403a**, the transistor **310** can have more stabilized electrical characteristics; thus, a highly reliable semiconductor device can be provided.

The third oxide semiconductor layer **403c** provided on the back-channel side of the second oxide semiconductor layer **403b** reduces the influence of a trap level at the back-channel-side interface of the transistor **310**. For example, the third oxide semiconductor layer **403c** can prevent a constituent element of the electrode layers **445a** and **445b** from diffusing into the second oxide semiconductor layer **403b**. That is, the third oxide semiconductor layer **403c** might contain the constituent element (e.g., copper) of the electrode layers **445a** and **445b**, as an impurity. Since formation of a trap level in the channel of the transistor can be prevented when the third oxide semiconductor layer **403c** is provided, an increase in S value due to the trap level and/or control of the threshold voltage can be performed. When the threshold voltage is controlled with the third oxide semiconductor layer **403c**, the transistor can be made normally off.

An example of a method for manufacturing the transistor **310** is described below.

First, the gate electrode layer **401** (including a wiring formed with the same layer) is formed over the substrate **400** having an insulating surface.

Next, the gate insulating layer **402** is provided over the gate electrode layer **401** so as to cover the gate electrode layer **401**. Note that it is preferable that a region which is included in the gate insulating layer **402** and is in contact with the first oxide semiconductor layer **403a** formed later (in this embodiment, the gate insulating layer **402b**) be formed using an oxide insulating layer and it is further preferable that the region include a region containing oxygen in a proportion higher

than that of the stoichiometric composition (an oxygen-excess region). In this embodiment, a silicon nitride film is formed as the gate insulating layer **402a**, and a silicon oxide film is formed as the gate insulating layer **402b**.

The gate insulating layer **402** does not have to be a stacked layer. For example, a 20-nm-thick silicon oxide film formed by a plasma CVD method may be used for the gate insulating layer **402**. In this case, after the silicon oxide film is formed, radical oxidation treatment using microwave plasma for reducing oxygen vacancies is preferably performed. For the conditions of the treatment, for example, a high-density plasma apparatus is used, a power of 3800 W is supplied with a power supply of 2.45 GHz, the pressure is 106.67 Pa, the substrate temperature is 325° C., the flow rate of argon is 900 sccm, and the flow rate of oxygen is 5 sccm. Here, a high-density plasma apparatus refers to an apparatus which can realize a plasma density higher than or equal to $1 \times 10^{11}/\text{cm}^3$. For example, plasma is generated by applying a microwave power of 3 kW to 6 kW inclusive. Further, before the gate insulating layer **402** is formed, plasma treatment in which nitrous oxide (N_2O) and a rare gas are introduced and a high-density plasma is used may be performed.

Next, the stack **403** of oxide semiconductor layers is formed over the gate insulating layer **402**. The stack **403** of oxide semiconductor layers has a three-layer structure in which the first oxide semiconductor layer **403a**, the second oxide semiconductor layer **403b**, and the third oxide semiconductor layer **403c** are stacked in this order. In this embodiment, the oxide semiconductor layer **403a** is formed using a target having an atomic ratio of In:Ga:Zn=1:3:2. The second oxide semiconductor layer **403b** is formed using a target having an atomic ratio of In:Ga:Zn=3:1:2. The third oxide semiconductor layer **403c** is formed using a target having an atomic ratio of In:Ga:Zn=1:1:1.

Next, a conductive film is formed over the stack **403** of oxide semiconductor layers and processed to form the electrode layer **445a** and the electrode layer **445b** (including a wiring formed with the same layer). Then, wet etching using dilute hydrofluoric acid is performed so that part of the third oxide semiconductor layer **403c** is thinned.

Next, the insulating layer **407** is formed to cover the electrode layer **445a**, the electrode layer **445b**, and the exposed stack **403** of oxide semiconductor layers. The insulating layer **407** can be formed using a single layer or a stack of layers of one or more of the following films formed by a plasma CVD method or a sputtering method: a silicon oxide film, a gallium oxide film, an aluminum oxide film, a silicon nitride film, a silicon oxynitride film, an aluminum oxynitride film, a silicon nitride oxide film, and the like. Note that it is preferable that an oxide insulating layer be formed as the insulating layer **407** (in this embodiment, the insulating layer **407a**) in contact with the stack **403** of oxide semiconductor layers because the oxide insulating layer can supply oxygen to the stack **403** of oxide semiconductor layers.

After the formation of the oxide insulating layer in which oxygen is diffused, a silicon oxide film or a silicon oxynitride film may be formed under the following conditions: the substrate placed in a treatment chamber of the plasma CVD apparatus, which is vacuum-evacuated, without exposure to the air is held at a temperature higher than or equal to 180° C. and lower than or equal to 250° C., preferably higher than or equal to 180° C. and lower than or equal to 230° C., the pressure in the treatment chamber is greater than or equal to 100 Pa and less than or equal to 250 Pa, preferably greater than or equal to 100 Pa and less than or equal to 200 Pa with introduction of a source gas into the treatment chamber, and high-frequency power higher than or equal to 0.17 W/cm² and

lower than or equal to 0.5 W/cm², preferably higher than or equal to 0.26 W/cm² and lower than or equal to 0.35 W/cm² is supplied to an electrode provided in the treatment chamber. Under the above conditions, the decomposition efficiency of the source gas in plasma is enhanced, oxygen radicals are increased, and oxidation of the source gas is promoted; thus, the oxygen content in the formed silicon oxide film or silicon oxynitride film is in excess of that in the stoichiometric composition. However, the bonding strength of silicon and oxygen is weak in the above substrate temperature range; therefore, part of oxygen is released by heating. Thus, it is possible to form an oxide insulating layer which contains oxygen in a proportion higher than that of oxygen in the stoichiometric composition and from which part of oxygen is released by heating.

In this embodiment, the silicon oxide film in which oxygen is diffused and the silicon oxide film from which part of oxygen is released by heating, which are described above, is formed as the insulating layer **407a**, and a silicon nitride film is formed as the insulating layer **407b**.

Heat treatment may be performed after the insulating layer **407** is formed. The temperature of the heat treatment is typically higher than or equal to 150° C. and lower than the strain point of the substrate, preferably higher than or equal to 200° C. and lower than or equal to 450° C., more preferably higher than or equal to 300° C. and lower than or equal to 450° C.

Through the above steps, the transistor **310** of this embodiment can be formed.

In the transistor described in this embodiment, the second oxide semiconductor layer **403b** which functions as a current path (channel) of the transistor is sandwiched between the first oxide semiconductor layer **403a** and the third oxide semiconductor layer **403c** which have lower carrier densities than the second oxide semiconductor layer **403b**. In this structure, the channel can be formed away from the interface with the insulating layer in contact with the stack **403** of oxide semiconductor layers, i.e., a buried channel can be formed; thus, the field-effect mobility of the transistor can be improved.

Further, this structure prevents formation of a trap level at the interface of the second oxide semiconductor layer **403b** functioning as the channel, and thus enables the transistor to have high reliability.

The structures, methods, and the like described in this embodiment can be combined as appropriate with any of the structures, methods, and the like described in the other embodiments.

(Embodiment 8)

A semiconductor device having a display function (also referred to as a display device) can be manufactured using the transistor described in Embodiment 1 or 7. Further, part or all of the driver circuitry which includes the transistor can be formed over a substrate where a pixel portion is formed, whereby a system-on-panel can be formed.

In FIG. 11A, a sealant **4005** is provided so as to surround a pixel portion **4002** provided over a substrate **4001**, and the pixel portion **4002** is sealed with a substrate **4006**. In FIG. 11A, a scan line driver circuit **4004** and a signal line driver circuit **4003** which are each formed using a single crystal semiconductor film or a polycrystalline semiconductor film over an IC chip or a substrate separately prepared are mounted on the substrate **4001**, in a region that is different from the region surrounded by the sealant **4005**. Various signals and potentials are supplied to the pixel portion **4002** through the signal line driver circuit **4003** and the scan line driver circuit **4004** from flexible printed circuits (FPCs) **4018a** and **4018b**.

In FIGS. 11B and 11C, the sealant **4005** is provided to surround the pixel portion **4002** and the scan line driver circuit **4004** which are provided over the substrate **4001**. The substrate **4006** is provided over the pixel portion **4002** and the scan line driver circuit **4004**. Consequently, the pixel portion **4002** and the scan line driver circuit **4004** are sealed together with a display element by the substrate **4001**, the sealant **4005**, and the substrate **4006**. In FIGS. 11B and 11C, the signal line driver circuit **4003** which is formed using a single crystal semiconductor film or a polycrystalline semiconductor film over an IC chip or a substrate separately prepared is mounted on the substrate **4001**, in a region that is different from the region surrounded by the sealant **4005**. In FIGS. 11B and 11C, various signals and potentials are supplied to the pixel portion **4002** through the signal line driver circuit **4003** and the scan line driver circuit **4004** from an FPC **4018**.

Although FIGS. 11B and 11C each illustrate an example in which the signal line driver circuit **4003** is formed separately and mounted on the substrate **4001**, one embodiment of the present invention is not limited to this structure. The scan line driver circuit may be separately formed and then mounted, or only part of the signal line driver circuit or part of the scan line driver circuit may be separately formed and then mounted.

Note that a connection method of a separately formed driver circuit is not particularly limited, and a chip on glass (COG) method, a wire bonding method, a tape automated bonding (TAB) method, or the like can be used. FIG. 11A shows an example in which the signal line driver circuit **4003** and the scan line driver circuit **4004** are mounted by a COG method. FIG. 11B shows an example in which the signal line driver circuit **4003** is mounted by a COG method. FIG. 11C shows an example in which the signal line driver circuit **4003** is mounted by a TAB method.

Note that the display device includes in its category a panel in which the display element is sealed and a module in which an IC including a controller or the like is mounted on the panel. That is, a display device in this specification means an image display device, a display device, or a light source (including a lighting device). Furthermore, the display device also includes the following modules in its category: a module to which a connector such as an FPC, a TAB, or a TCP is attached; a module having a TAB or a TCP at the tip of which a printed wiring board is provided; and a module in which an integrated circuit (IC) is directly mounted on a display element by a COG method.

The pixel portion and the scan line driver circuit provided over the substrate include a plurality of transistors, and the transistor described in Embodiment 1 or 7 can be applied thereto.

As the display element provided in the display device, a liquid crystal element (also referred to as a liquid crystal display element) or a light-emitting element (also referred to as a light-emitting display element) can be used. The light-emitting element includes, in its category, an element whose luminance is controlled by current or voltage, and specifically includes an inorganic electroluminescent (EL) element, an organic EL element, and the like. Furthermore, a display medium whose contrast is changed by an electric effect, such as an electronic ink display device (electronic paper), can be used.

Embodiments of the semiconductor device are described with reference to FIGS. 11A to 11C and FIGS. 12A and 12B. FIGS. 12A and 12B correspond to cross-sectional views along line M-N in FIG. 11B. Examples of a liquid crystal display device using a liquid crystal element as a display element are illustrated in FIGS. 12A and 12B.

A liquid crystal display device can employ a vertical electric field mode or a horizontal electric field mode. FIG. 12A illustrates an example in which a vertical electric field mode is employed, and FIG. 12B illustrates an example in which a fringe field switching (FFS) mode, which is one of horizontal electric field modes, is employed.

Note that a transistor **4010** provided in the pixel portion **4002** is electrically connected to a display element to form a display panel. A variety of display elements can be used as the display element as long as display can be performed.

As illustrated in FIGS. 11A to 11C and FIGS. 12A and 12B, the semiconductor device includes a connection terminal electrode **4015** and a terminal electrode **4016**. The connection terminal electrode **4015** and the terminal electrode **4016** are electrically connected to a terminal included in the FPC **4018** or **4018b** through an anisotropic conductive layer **4019**.

The connection terminal electrode **4015** is formed from the same conductive layer as a first electrode layer **4034**. The terminal electrode **4016** is formed from the same conductive layer as a gate electrode layer of the transistor **4010** and a transistor **4011**.

The pixel portion **4002** and the scan line driver circuit **4004** provided over the substrate **4001** include a plurality of transistors. FIGS. 11A to 11C and FIGS. 12A and 12B illustrate the transistor **4010** included in the pixel portion **4002** and the transistor **4011** included in the scan line driver circuit **4004**. In FIGS. 12A and 12B, insulating layers **4032a** and **4032b** are provided over the transistors **4010** and **4011**.

In FIG. 12B, a planarization insulating layer **4040** is provided over the insulating layer **4032b**, and an insulating layer **4042** is provided between the first electrode layer **4034** and the second electrode layer **4031**.

The transistor described in Embodiment 1 or 7 can be applied to the transistor **4010** and the transistor **4011**. In this embodiment, an example in which a transistor having a structure similar to that of the transistor **310** described in Embodiment 7 is used is described. The transistors **4010** and **4011** are bottom-gate transistors.

The transistors **4010** and **4011** each include a stacked-layer structure of a gate insulating layers **4020a** and **4020b**. In FIG. 12A, the gate insulating layers **4020a** and **4020b** of the transistors **4010** and **4011** and the insulating layers **4032a** and **4032b** provided over the transistors **4010** and **4011** extend below the sealant **4005** to cover an end portion of the connection terminal electrode **4015**. In FIG. 12B, the gate insulating layer **4020a** and the insulating layer **4032b** extend below the sealant **4005** to cover the end portion of the connection terminal electrode **4015**, and the insulating layer **4032b** covers side surfaces of the gate insulating layer **4020b** and the insulating layer **4032a**. It is preferable to apply of a film (e.g., a silicon nitride film) having a blocking property against hydrogen or a compound containing hydrogen (e.g., water) to each of the gate insulating layer **4020a** and the insulating layer **4032b** because the film can prevent the entry of hydrogen or a compound containing hydrogen from the air or the like, resulting in an improvement in the reliability of the semiconductor device.

In each of the transistors **4010** and **4011**, a second oxide semiconductor layer which functions as a current path (channel) is sandwiched between a first oxide semiconductor layer and a third oxide semiconductor layer which have different compositions from the second oxide semiconductor layer. Accordingly, each of the transistors **4010** and **4011** is a buried-channel transistor in which a current path is formed away from the interface with the insulating layer, and therefore has high field-effect mobility. In addition, each of the transistors

4010 and **4011** is a highly reliable transistor in which influence of an interface state which might be formed on the back channel side is reduced and photodegradation (e.g., negative-bias temperature stress photodegradation) is reduced.

Moreover, a conductive layer may be further provided so as to overlap with a channel formation region in the oxide semiconductor layer of the transistor **4011** for the driver circuit. When the conductive layer is provided so as to overlap with the channel formation region in the oxide semiconductor layer, the amount of change in the threshold voltage of the transistor **4011** can be further reduced. The conductive layer may have the same potential as or a potential different from that of a gate electrode layer of the transistor **4011**, and can function as a second gate electrode layer. The potential of the conductive layer may be a minimum potential, GND, or 0 V, or the conductive layer may be in a floating state.

In addition, the conductive layer has a function of blocking an external electric field, that is, a function of preventing an external electric field (particularly, a function of preventing static electricity) from affecting the inside (a circuit portion including a transistor). A blocking function of the conductive layer can prevent variation in the electrical characteristics of the transistor due to an influence of an external electric field such as static electricity.

In FIGS. **12A** and **12B**, a liquid crystal element **4013** includes a first electrode layer **4034**, a second electrode layer **4031**, and a liquid crystal layer **4008**. Note that insulating layers **4033** and **4038** functioning as alignment films are provided so that the liquid crystal layer **4008** is positioned therebetween.

In FIG. **12A**, the second electrode layer **4031** is provided on the substrate **4006** side, and the first electrode layer **4034** and the second electrode layer **4031** are stacked with the liquid crystal layer **4008** provided therebetween. In FIG. **12B**, the second electrode layer **4031** having an opening pattern is provided below the liquid crystal layer **4008**, and the first electrode layer **4034** having a flat plate shape is provided below the second electrode layer **4031** with the insulating layer **4042** provided therebetween. In FIG. **12B**, the second electrode layer **4031** having an opening pattern includes a bent portion or a comb-shaped portion. An arrangement of the first electrode layer **4034** and the second electrode layer **4031**, which complies with both conditions that they have the same shape and they completely overlap with each other, is avoided in order to generate an electric field between the electrodes. Note that a structure may be employed in which the second electrode layer **4031** having a flat plate shape is formed on and in contact with the planarization insulating layer **4040**, and the first electrode layer **4034** having an opening pattern and serving as a pixel electrode is formed over the second electrode layer **4031** with the insulating layer **4042** provided therebetween.

The first electrode layer **4034** and the second electrode layer **4031** can be formed using a light-transmitting conductive material such as indium oxide containing tungsten oxide, indium zinc oxide containing tungsten oxide, indium oxide containing titanium oxide, indium tin oxide containing titanium oxide, indium tin oxide, indium zinc oxide, indium tin oxide to which silicon oxide is added, or graphene.

Alternatively, the first electrode layer **4034** and the second electrode layer **4031** can be formed using one or more materials selected from metals such as tungsten (W), molybdenum (Mo), zirconium (Zr), hafnium (Hf), vanadium (V), niobium (Nb), tantalum (Ta), chromium (Cr), cobalt (Co), nickel (Ni), titanium (Ti), platinum (Pt), aluminum (Al), copper (Cu), and silver (Ag); an alloy of any of these metals; and a nitride of any of these metals.

A spacer **4035** is a columnar spacer obtained by selective etching of an insulating layer and is provided in order to control the thickness of the liquid crystal layer **4008** (a cell gap). Alternatively, a spherical spacer may be used.

In the case where a liquid crystal element is used as the display element, a thermotropic liquid crystal, a ferroelectric liquid crystal, an anti-ferroelectric liquid crystal, or the like can be used. These liquid crystal materials may be a low molecular compound or a high molecular compound. Such a liquid crystal material (liquid crystal composition) exhibits a cholesteric phase, a smectic phase, a cubic phase, a chiral nematic phase, an isotropic phase, or the like depending on conditions.

Alternatively, a liquid crystal composition exhibiting a blue phase for which an alignment film is unnecessary may be used for the liquid crystal layer **4008**. In this case, the liquid crystal layer **4008** is in contact with the first electrode layer **4034** and the second electrode layer **4031**. A blue phase is one of liquid crystal phases, which is generated just before a cholesteric phase changes into an isotropic phase while temperature of cholesteric liquid crystal is increased. The blue phase can be exhibited using a liquid crystal composition which is a mixture of a liquid crystal and a chiral material. In order to increase the temperature range where the blue phase is exhibited, a liquid crystal layer may be formed by adding a polymerizable monomer, a polymerization initiator, and the like to a liquid crystal composition exhibiting a blue phase and by performing polymer stabilization treatment. The liquid crystal composition exhibiting a blue phase has a short response time, and has optical isotropy, which contributes to the exclusion of the alignment process and reduction of viewing angle dependence. In addition, since an alignment film does not need to be provided and rubbing treatment is unnecessary, electrostatic discharge damage caused by the rubbing treatment can be prevented and defects and damage of the liquid crystal display device can be reduced in the manufacturing process. Thus, productivity of the liquid crystal display device can be increased.

The specific resistivity of the liquid crystal material is greater than or equal to $1 \times 10^9 \Omega \cdot \text{cm}$, preferably greater than or equal to $1 \times 10^{11} \Omega \cdot \text{cm}$, more preferably greater than or equal to $1 \times 10^{12} \Omega \cdot \text{cm}$. Note that the specific resistivity in this specification is measured at 20° C.

The size of a storage capacitor formed in the liquid crystal display device is set considering the leakage current of the transistor provided in the pixel portion or the like so that charge can be held for a predetermined period. The size of the storage capacitor may be set considering the off-state current of a transistor or the like. By using a transistor including an oxide semiconductor layer, which is disclosed in this specification, it is enough to provide a storage capacitor having a capacitance that is $\frac{1}{3}$ or less, preferably $\frac{1}{5}$ or less of liquid crystal capacitance of each pixel.

In the transistor including an oxide semiconductor layer, which is disclosed in this specification, the current in an off state (off-state current) can be made small. Accordingly, an electric signal such as an image signal can be held for a longer period and a writing interval can be set longer. Accordingly, the frequency of refresh operation can be reduced, which leads to an effect of suppressing power consumption.

The transistor including an oxide semiconductor layer, which is disclosed in this specification, can have high field-effect mobility; thus, the transistor can operate at high speed. For example, when such a transistor is used for a liquid crystal display device, a switching transistor in a pixel portion and a driver transistor in a driver circuit portion can be formed over

one substrate. In addition, by using such a transistor in a pixel portion, a high-quality image can be provided.

For the liquid crystal display device, a twisted nematic (TN) mode, an in-plane-switching (IPS) mode, an axially symmetric aligned micro-cell (ASM) mode, an optical compensated birefringence (OCB) mode, a ferroelectric liquid crystal (FLC) mode, an anti-ferroelectric liquid crystal (AFLC) mode, or the like can be used.

A normally black liquid crystal display device such as a transmissive liquid crystal display device utilizing a vertical alignment (VA) mode may be used. Some examples are given as the vertical alignment mode. For example, a multi-domain vertical alignment (MVA) mode, a patterned vertical alignment (PVA) mode, or an advanced super view (ASV) mode can be used. Furthermore, this embodiment can be applied to a VA liquid crystal display device. The VA liquid crystal display device has a kind of form in which alignment of liquid crystal molecules of a liquid crystal display panel is controlled. In the VA liquid crystal display device, liquid crystal molecules are aligned in a vertical direction with respect to a panel surface when no voltage is applied. Moreover, it is possible to use a method called domain multiplication or multi-domain design, in which a pixel is divided into some regions (subpixels) and molecules are aligned in different directions in their respective regions.

In the display device, a black matrix (a light-blocking layer), an optical member (an optical substrate) such as a polarizing member, a retardation member, or an anti-reflection member, and the like are provided as appropriate. For example, circular polarization may be obtained by using a polarizing substrate and a retardation substrate. In addition, a backlight, a side light, or the like may be used as a light source.

As a display method in the pixel portion, a progressive method, an interlace method or the like can be employed. Further, color elements controlled in a pixel at the time of color display are not limited to three colors: R, G, and B (R, G, and B correspond to red, green, and blue, respectively). For example, R, G, B, and W (W corresponds to white); R, G, B, and one or more of yellow, cyan, magenta, and the like; or the like can be used. Further, the sizes of display regions may be different between respective dots of color elements. Note that one embodiment of the disclosed invention is not limited to the application to a display device for color display; the disclosed invention can also be applied to a display device for monochrome display.

Alternatively, as the display element included in the display device, a light-emitting element utilizing electroluminescence can be used. Light-emitting elements utilizing electroluminescence are classified according to whether a light-emitting material is an organic compound or an inorganic compound. In general, the former is referred to as an organic EL element, and the latter is referred to as an inorganic EL element.

In an organic EL element, by application of voltage to a light-emitting element, electrons and holes are separately injected from a pair of electrodes into a layer containing a light-emitting organic compound, and current flows. The carriers (electrons and holes) are recombined, and thus, the light-emitting organic compound is excited. The light-emitting organic compound returns to a ground state from the excited state, thereby emitting light. Owing to such a mechanism, this light-emitting element is referred to as a current-excitation light-emitting element. In this embodiment, an organic EL element is used as a light-emitting element.

In order to extract light emitted from the light-emitting element, at least one of the pair of electrodes has a light-

transmitting property. A transistor and a light-emitting element are formed over a substrate. The light-emitting element can have a top emission structure in which light emission is extracted through the surface opposite to the substrate; a bottom emission structure in which light emission is extracted through the surface on the substrate side; or a dual emission structure in which light emission is extracted through the surface opposite to the substrate and the surface on the substrate side, and a light-emitting element having any of these emission structures can be used.

FIGS. 13A and 13B illustrate an example of a light-emitting device using a light-emitting element as a display element.

FIG. 13A is a plan view of the light-emitting device, and FIG. 13B is a cross-sectional view taken along dashed-dotted lines S1-T1, S2-T2, and S3-T3 in FIG. 13A. Note that an electroluminescent layer 542 and a second electrode layer 543 are not illustrated in the plan view in FIG. 13A.

The light-emitting device illustrated in FIGS. 13A and 13B includes, over a substrate 500, a transistor 510, a capacitor 520, and a wiring layer intersection 530. The transistor 510 is electrically connected to a light-emitting element 540. Note that FIGS. 13A and 13B illustrate a bottom-emission light-emitting device in which light from the light-emitting element 540 is extracted through the substrate 500.

The transistor described in Embodiment 1 or 7 can be applied to the transistor 510. In this embodiment, an example in which a transistor having a structure similar to that of the transistor 310 described in Embodiment 7 is used is described. The transistor 510 is a bottom-gate transistor.

The transistor 510 includes gate electrode layers 511a and 511b; gate insulating layers 501 and 502; an stack of oxide semiconductor layers 512 including a first oxide semiconductor layer 512a, a second oxide semiconductor layer 512b, and a third oxide semiconductor layer 512c; and conductive layers 513a and 513b serving as a source electrode layer and a drain electrode layer. In addition, an insulating layer 525 is formed over the transistor 510.

The capacitor 520 includes conductive layers 521a and 521b; the gate insulating layers 501 and 502; a stack of oxide semiconductor layers 522 including a first oxide semiconductor layer 522a, a second oxide semiconductor layer 522b, and a third oxide semiconductor layer 522c; and a conductive layer 523. The gate insulating layers 501 and 502 and the stack of oxide semiconductor layers 522 are sandwiched between the conductive layer 523 and the conductive layers 521a and 521b, whereby the capacitor is formed.

The wiring layer intersection 530 is an intersection of a conductive layer 533 and the gate electrode layers 511a and 511b. The conductive layer 533 and the gate electrode layers 511a and 511b intersect with each other with the gate insulating layers 501 and 502 provided therebetween.

In this embodiment, a 30-nm-thick titanium film is used as each of the gate electrode layer 511a and the conductive layer 521a, and a 200-nm-thick copper film is used as each of the gate electrode layer 511b and the conductive layer 521b. Thus, the gate electrode layer has a stacked-layer structure of the titanium film and the copper film.

In the transistor 510, a second oxide semiconductor layer which functions as a current path (channel) is sandwiched between a first oxide semiconductor layer and a third oxide semiconductor layer which have different compositions from the second oxide semiconductor layer. Accordingly, the transistor 510 is a buried-channel transistor in which a current path is formed away from the interface with the insulating layer, and therefore has high field-effect mobility. In addition, the transistor 510 is a highly reliable transistor in which

influence of an interface state which might be formed on the back channel side is reduced and photodegradation (e.g., negative-bias temperature stress photodegradation) is reduced.

An interlayer insulating layer **504** is formed over the transistor **510**, the capacitor **520**, and the wiring layer intersection **530**. Over the interlayer insulating layer **504**, a color filter layer **505** is provided in a region overlapping with the light-emitting element **540**. An insulating layer **506** functioning as a planarization insulating layer is provided over the interlayer insulating layer **504** and the color filter layer **505**.

The light-emitting element **540** having a stacked-layer structure in which a first electrode layer **541**, the electroluminescent layer **542**, and the second electrode layer **543** are stacked in this order is provided over the insulating layer **506**. The first electrode layer **541** and the conductive layer **513a** are in contact with each other in an opening formed in the insulating layer **506** and the interlayer insulating layer **504**, which reaches the conductive layer **513a**; thus the light-emitting element **540** and the transistor **510** are electrically connected to each other. Note that a partition **507** is provided so as to cover part of the first electrode layer **541** and the opening.

Further, a 1500-nm-thick photosensitive acrylic film and a 1500-nm-thick photosensitive polyimide film can be used as the insulating layer **506** and the partition **507**, respectively.

As the color filter layer **505**, for example, a chromatic color light-transmitting resin can be used. As the chromatic color light-transmitting resin, a photosensitive organic resin or a non-photosensitive organic resin can be used. The photosensitive organic resin is preferably used, in which case the number of resist masks can be reduced, which results in the simplification of the process.

Chromatic colors are all colors except achromatic colors such as black, gray, and white. The color filter layer is formed using a material which transmits only light of the chromatic colors. As chromatic color, red, green, blue, or the like can be used. Alternatively, cyan, magenta, yellow, or the like may also be used. "Transmitting only light of a chromatic color" means that light passing through the color filter layer has a peak at a wavelength of the light of the chromatic color. The thickness of the color filter layer may be controlled as appropriate in consideration of the relationship between the concentration of the coloring material to be included and the transmittance of light. For example, the color filter layer **505** may have a thickness greater than or equal to 1500 nm and less than or equal to 2000 nm.

The partition **507** can be formed using an organic insulating material or an inorganic insulating material. It is particularly preferable that the partition **507** be formed using a photosensitive resin material to have an opening over the first electrode layer **541**. A sidewall of the opening is preferably formed as a tilted surface with continuous curvature.

The electroluminescent layer **542** may be formed using either a single layer or a stack of a plurality of layers.

A protective film may be formed over the second electrode layer **543** and the partition **507** in order to prevent entry of oxygen, hydrogen, moisture, carbon dioxide, or the like into the light-emitting element **540**. As the protective film, a silicon nitride film, a silicon nitride oxide film, a DLC film, or the like can be formed.

Further, the light-emitting element **540** may be covered with a layer containing an organic compound deposited by an evaporation method so that oxygen, hydrogen, moisture, carbon dioxide, or the like do not enter the light-emitting element **540**.

In addition, if needed, an optical film, such as a polarizing plate, a circularly polarizing plate (including an elliptically polarizing plate), a retardation plate (a quarter-wave plate or a half-wave plate), or a color filter, may be provided as appropriate on a light-emitting surface of the light-emitting element. Further, the polarizing plate or the circularly polarizing plate may be provided with an anti-reflection film. For example, anti-glare treatment by which reflected light can be diffused by projections and depressions on the surface so as to reduce the glare can be performed.

The insulating layer **506** functioning as a planarization insulating layer can be formed using an organic material having heat resistance, such as an acrylic resin, polyimide, a benzocyclobutene-based resin, polyamide, or an epoxy resin. Other than such organic materials, it is also possible to use a low-dielectric constant material (low-k material) such as a siloxane-based resin, phosphosilicate glass (PSG), or borophosphosilicate glass (BPSG). Note that the insulating layer **506** may be formed by stacking a plurality of insulating layers formed using any of these materials.

There is no particular limitation on the method of forming the insulating layer **506**; the following method can be used depending on the material: a sputtering method, spin coating, dipping, spray coating, a droplet discharge method (such as an inkjet method), screen printing, offset printing, or the like.

Materials similar to those of the first electrode layer **4034** and the second electrode layer **4031** illustrated in FIG. 12A or FIG. 12B can be used for the first electrode layer **541** and the second electrode layer **543**.

In this embodiment, since the light-emitting device illustrated in FIGS. 13A and 13B has a bottom-emission structure, the first electrode layer **541** has a light-transmitting property and the second electrode layer **543** has a light-reflecting property. Accordingly, in the case of using a metal film as the first electrode layer **541**, the film is preferably made thin enough to secure a light-transmitting property; and in the case of using a light-transmitting conductive layer as the second electrode layer **543**, a light-reflecting conductive layer is preferably stacked therewith.

A protection circuit for protecting the driver circuit may be provided. The protection circuit is preferably formed using a nonlinear element.

By using the transistor described in Embodiment 7 as described above, the semiconductor device can have a variety of functions.
(Embodiment 9)

A semiconductor device disclosed in this specification can be applied to a variety of electronic devices (including game machines). Examples of the electronic devices include display devices of televisions, monitors, and the like, lighting devices, desktop personal computers and notebook personal computers, word processors, image reproduction devices which reproduce still images or moving images stored in recording media such as digital versatile discs (DVDs), portable compact disc (CD) players, radio receivers, tape recorders, headphone stereos, stereos, cordless phone handsets, transceivers, portable wireless devices, mobile phones, car phones, portable game machines, calculators, portable information terminals, electronic notebooks, e-book readers, electronic translators, audio input devices, video cameras, digital still cameras, electric shavers, high-frequency heating appliances such as microwave ovens, electric rice cookers, electric washing machines, electric vacuum cleaners, air-conditioning systems such as air conditioners, dishwashers, dish dryers, clothes dryers, futon dryers, electric refrigerators, electric freezers, electric refrigerator-freezers, freezers for preserving DNA, smoke detectors, radiation counters, and medical

equipment such as dialyzers. Further, the examples include industrial equipment such as guide lights, traffic lights, belt conveyors, elevators, escalators, industrial robots, and power storage systems. In addition, oil engines, moving objects driven by electric motors using power from the non-aqueous secondary batteries, and the like are also included in the category of electric appliances. Examples of the moving objects include electric vehicles (EV), hybrid electric vehicles (HEV) which include both an internal-combustion engine and a motor, plug-in hybrid electric vehicles (PHEV), tracked vehicles in which caterpillar tracks are substituted for wheels of these vehicles, motorized bicycles including motor-assisted bicycles, motorcycles, electric wheelchairs, golf carts, boats or ships, submarines, helicopters, aircrafts, rockets, artificial satellites, space probes, planetary probes, spacecrafts, and the like. Specific examples of these electronic devices are illustrated in FIGS. 14A to 14C and FIGS. 15A to 15C.

FIGS. 14A and 14B illustrate a tablet terminal that can be folded in two. FIG. 14A illustrates the tablet terminal which is open (unfolded). The tablet terminal includes a housing 9630, a display portion 9631a, a display portion 9631b, a switch 9034 for switching display modes, a power switch 9035, a switch 9036 for switching to power-saving mode, a fastener 9033, and an operation switch 9038.

In such a portable device illustrated in FIGS. 14A and 14B, an SRAM or a DRAM is used as a memory for temporarily storing image data. For example, the semiconductor device described in Embodiment 5 can be used as a memory. The semiconductor device described in the above embodiment employed for the memory element enables writing and reading of data to be performed at high speed, enables data to be retained for a long time, and enables power consumption to be sufficiently reduced. A CPU for performing image processing or arithmetic processing is used in the portable device illustrated in FIGS. 14A and 14B. As the CPU, the CPU described in Embodiment 6 can be used. In the case where the CPU described in Embodiment 6 is used, power consumption of the portable device can be reduced.

A touch panel region 9632a can be provided in a part of the display portion 9631a, in which data can be input by touching displayed operation keys 9638. Note that FIG. 14A shows, as an example, that half of the area of the display portion 9631a has only a display function and the other half of the area has a touch panel function. However, the structure of the display portion 9631a is not limited to this, and all the area of the display portion 9631a may have a touch panel function. For example, all the area of the display portion 9631a can display keyboard buttons and serve as a touch panel while the display portion 9631b can be used as a display screen.

Like the display portion 9631a, part of the display portion 9631b can be a touch panel region 9632b. When a finger, a stylus, or the like touches the place where a button 9639 for switching to keyboard display is displayed in the touch panel, keyboard buttons can be displayed on the display portion 9631b.

Touch input can be performed concurrently on the touch panel regions 9632a and 9632b.

The switch 9034 for switching display modes allows switching between a landscape mode and a portrait mode, color display and black-and-white display, and the like. With the switch 9036 for switching to power-saving mode, the luminance of display can be optimized in accordance with the amount of external light at the time when the tablet is in use, which is detected with an optical sensor incorporated in the tablet. The tablet terminal may include another detection

device such as a sensor for detecting orientation (e.g., a gyroscope or an acceleration sensor) in addition to the optical sensor.

Although FIG. 14A shows the example where the display area of the display portion 9631a is the same as that of the display portion 9631b, there is no particular limitation on the display portions 9631a and 9631b. They may differ in size and/or image quality. For example, one of them may be a display panel that can display higher-definition images than the other.

FIG. 14B illustrates the tablet terminal which is closed. The tablet terminal includes the housing 9630, a solar battery 9633, a charge/discharge control circuit 9634, a battery 9635, and a DC-DC converter 9636. As an example, FIG. 14B illustrates the charge/discharge control circuit 9634 including the battery 9635 and the DC-DC converter 9636.

Since the tablet terminal can be folded in two, the housing 9630 can be closed when the tablet is not in use. Thus, the display portions 9631a and 9631b can be protected, thereby providing a tablet terminal with high endurance and high reliability for long-term use.

The tablet terminal illustrated in FIGS. 14A and 14B can also have a function of displaying various kinds of data (e.g., a still image, a moving image, and a text image), a function of displaying a calendar, a date, the time, or the like on the display portion, a touch-input function of operating or editing data displayed on the display portion by touch input, a function of controlling processing by various kinds of software (programs), and the like.

The solar battery 9633, which is attached on the surface of the tablet terminal, supplies electric power to a touch panel, a display portion, an image signal processor, and the like. Note that the solar battery 9633 can be provided on one or both surfaces of the housing 9630 and the battery 9635 can be charged efficiently. When a lithium ion battery is used as the battery 9635, there is an advantage of downsizing or the like.

The structure and operation of the charge/discharge control circuit 9634 illustrated in FIG. 14B are described with reference to a block diagram in FIG. 14C. FIG. 14C illustrates the solar battery 9633, the battery 9635, the DC-DC converter 9636, a converter 9637, switches SW1 to SW3, and the display portion 9631. The battery 9635, the DC-DC converter 9636, the converter 9637, and the switches SW1 to SW3 correspond to the charge/discharge control circuit 9634 illustrated in FIG. 14B.

First, an example of operation in the case where power is generated by the solar battery 9633 using external light is described. The voltage of power generated by the solar battery 9633 is raised or lowered by the DC-DC converter 9636 so that a voltage for charging the battery 9635 is obtained. When the display portion 9631 is operated with the power from the solar battery 9633, the switch SW1 is turned on and the voltage of the power is raised or lowered by the converter 9637 to a voltage needed for operating the display portion 9631. In addition, when display on the display portion 9631 is not performed, the switch SW1 is turned off and a switch SW2 is turned on so that charge of the battery 9635 may be performed.

Here, the solar battery 9633 is shown as an example of a power generation means; however, there is no particular limitation on a way of charging the battery 9635, and the battery 9635 may be charged with another power generation means such as a piezoelectric element or a thermoelectric conversion element (Peltier element). For example, the battery 9635 may be charged with a non-contact power transmission module

39

that transmits and receives power wirelessly (without contact) to charge the battery or with a combination of other charging means.

In a television set **8000** in FIG. **15A**, a display portion **8002** is incorporated in a housing **8001**. The display portion **8002** displays an image and a speaker portion **8003** can output sound.

A display device such as a liquid crystal display device, a light-emitting device in which a light-emitting element such as an organic EL element is provided in each pixel, or the like described in Embodiment 8 can be used for the display portion **8002**.

The television set **8000** may be provided with a receiver, a modem, and the like. With the receiver, the television set **8000** can receive general television broadcasting. Furthermore, when the television set **8000** is connected to a communication network by wired or wireless connection via the modem, one-way (from a transmitter to a receiver) or two-way (between a transmitter and a receiver, between receivers, or the like) data communication can be performed.

In addition, the television set **8000** may include a CPU for performing information communication or a memory. The memory described in Embodiment 4 or the CPU described in Embodiment 6 can be used in the television set **8000**.

In FIG. **15A**, an air conditioner which includes an indoor unit **8200** and an outdoor unit **8204** is an example of an electric appliance in which the CPU of Embodiment 6 is used. Specifically, the indoor unit **8200** includes a housing **8201**, an air outlet **8202**, a CPU **8203**, and the like. Although the CPU **8203** is provided in the indoor unit **8200** in FIG. **15A**, the CPU **8203** may be provided in the outdoor unit **8204**. Alternatively, the CPU **8203** may be provided in both the indoor unit **8200** and the outdoor unit **8204**. By using the CPU described in Embodiment 6 as the CPU in the air conditioner, power consumption can be reduced.

In FIG. **15A**, an electric refrigerator-freezer **8300** is an example of an electric appliance which is provided with the CPU formed using an oxide semiconductor. Specifically, the electric refrigerator-freezer **8300** includes a housing **8301**, a door for a refrigerator **8302**, a door for a freezer **8303**, a CPU **8304**, and the like. In FIG. **15A**, the CPU **8304** is provided in the housing **8301**. When the CPU described in Embodiment 6 is used as the CPU **8304** of the electric refrigerator-freezer **8300**, power consumption of the electric refrigerator-freezer **8300** can be reduced.

An example of an electric vehicle which is an example of an electric appliance is described in FIG. **15B**. An electric vehicle **9700** is equipped with a secondary battery **9701**. The output of power of the non-aqueous secondary battery **9701** is adjusted by a control circuit **9702** and the power is supplied to a driving device **9703**. The control circuit **9702** is controlled by a processing unit **9704** including a ROM, a RAM, a CPU, or the like which is not illustrated. When the CPU described in Embodiment 6 is used as the CPU in the electric vehicle **9700**, power consumption of the electric vehicle **9700** can be reduced.

The driving device **9703** includes a DC motor or an AC motor either alone or in combination with an internal-combustion engine. The processing unit **9704** outputs a control signal to the control circuit **9702** based on input data such as data of operation (e.g., acceleration, deceleration, or stop) by a driver or data during driving (e.g., data on an upgrade or a downgrade, or data on a load on a driving wheel) of the electric vehicle **9700**. The control circuit **9702** adjusts the electric energy supplied from the secondary battery **9701** in accordance with the control signal of the processing unit **9704** to control the output of the driving device **9703**. In the case

40

where the AC motor is mounted, although not illustrated, an inverter which converts direct current into alternate current is also incorporated.

This embodiment can be implemented in combination with any of the other embodiments, as appropriate.

This application is based on Japanese Patent Application serial No. 2012-152794 filed with Japan Patent Office on Jul. 6, 2012, the entire contents of which are hereby incorporated by reference.

What is claimed is:

1. A semiconductor device comprising:

a first insulating layer over an insulating surface;

a first oxide semiconductor layer over the first insulating layer;

a second oxide semiconductor layer over the first oxide semiconductor layer;

a third oxide semiconductor layer over the second oxide semiconductor layer;

a first electrode layer and a second electrode layer over the third oxide semiconductor layer; and

a second insulating layer over the third oxide semiconductor layer,

wherein the first oxide semiconductor layer, the second oxide semiconductor layer and the third oxide semiconductor layer comprise same constituent elements,

wherein a composition of the second oxide semiconductor layer is different from a composition of the first oxide semiconductor layer and a composition of the third oxide semiconductor layer, and

wherein an energy level of a bottom of a conductive band of the first oxide semiconductor layer is continuously changed to an energy level of a bottom of a conductive band of the second oxide semiconductor layer at an interface between the second oxide semiconductor layer and the first oxide semiconductor layer.

2. The semiconductor device according to claim 1, wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is lower than the energy level of the bottom of the conductive band of the first oxide semiconductor layer.

3. The semiconductor device according to claim 1, wherein the third oxide semiconductor layer is in direct contact with outer side surfaces of the first oxide semiconductor layer.

4. The semiconductor device according to claim 1, wherein the third oxide semiconductor layer is in direct contact with outer side surfaces of the second oxide semiconductor layer.

5. The semiconductor device according to claim 1, wherein a thickness of the first oxide semiconductor layer is smaller than a thickness of the second oxide semiconductor layer.

6. The semiconductor device according to claim 1, wherein a thickness of the first oxide semiconductor layer is smaller than a thickness of the third oxide semiconductor layer.

7. The semiconductor device according to claim 1, further comprising a gate electrode layer between the insulating surface and the first insulating layer.

8. The semiconductor device according to claim 1, further comprising a gate electrode layer over the second insulating layer.

9. The semiconductor device according to claim 1, further comprising:

a first gate electrode layer between the insulating surface and the first insulating layer, and

a second gate electrode layer over the second insulating layer.

10. The semiconductor device according to claim 1, further comprising a third insulating layer over the second insulating layer,

41

wherein the third insulating layer is a nitride insulating film, and
 wherein the second insulating layer is an oxide insulating film.

11. The semiconductor device according to claim 1, wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is continuously changed to an energy level of a bottom of a conductive band of the third oxide semiconductor layer at an interface between the second oxide semiconductor layer and the third oxide semiconductor layer.

12. The semiconductor device according to claim 11, wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is lower than the energy level of the bottom of the conductive band of the first oxide semiconductor layer, and wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is lower than the energy level of the bottom of the conductive band of the third oxide semiconductor layer.

13. A semiconductor device comprising:
 a first insulating layer over an insulating surface;
 a first oxide semiconductor layer over the first insulating layer;
 a second oxide semiconductor layer over the first oxide semiconductor layer;
 a third oxide semiconductor layer over the second oxide semiconductor layer;
 a first electrode layer and a second electrode layer over the third oxide semiconductor layer; and
 a second insulating layer over the third oxide semiconductor layer,
 wherein the first oxide semiconductor layer, the second oxide semiconductor layer and the third oxide semiconductor layer comprise same constituent elements,
 wherein a composition of the second oxide semiconductor layer is different from a composition of the first oxide semiconductor layer and a composition of the third oxide semiconductor layer,

wherein an energy level of a bottom of a conductive band of the first oxide semiconductor layer is continuously changed to an energy level of a bottom of a conductive band of the second oxide semiconductor layer at an interface between the second oxide semiconductor layer and the first oxide semiconductor layer, and
 wherein a thickness of a region of the first insulating layer which overlaps with the first oxide semiconductor layer is larger than a thickness of a region of the first insulating layer which does not overlap with the first oxide semiconductor layer.

14. The semiconductor device according to claim 13, wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is lower than the energy level of the bottom of the conductive band of the first oxide semiconductor layer.

42

15. The semiconductor device according to claim 13, wherein the third oxide semiconductor layer is in direct contact with outer side surfaces of the first oxide semiconductor layer.

16. The semiconductor device according to claim 13 wherein the third oxide semiconductor layer is in direct contact with outer side surfaces of the second oxide semiconductor layer.

17. The semiconductor device according to claim 13, wherein a thickness of the first oxide semiconductor layer is smaller than a thickness of the second oxide semiconductor layer.

18. The semiconductor device according to claim 13, wherein a thickness of the first oxide semiconductor layer is smaller than a thickness of the third oxide semiconductor layer.

19. The semiconductor device according to claim 13, further comprising a gate electrode layer between the insulating surface and the first insulating layer.

20. The semiconductor device according to claim 13, further comprising a gate electrode layer over the second insulating layer.

21. The semiconductor device according to claim 13, further comprising:

a first gate electrode layer between the insulating surface and the first insulating layer, and

a second gate electrode layer over the second insulating layer.

22. The semiconductor device according to claim 13, further comprising a third insulating layer over the second insulating layer,

wherein the third insulating layer is a nitride insulating film, and

wherein the second insulating layer is an oxide insulating film.

23. The semiconductor device according to claim 13, wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is continuously changed to an energy level of a bottom of a conductive band of the third oxide semiconductor layer at an interface between the second oxide semiconductor layer and the third oxide semiconductor layer.

24. The semiconductor device according to claim 23, wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is lower than the energy level of the bottom of the conductive band of the first oxide semiconductor layer, and
 wherein the energy level of the bottom of the conductive band of the second oxide semiconductor layer is lower than the energy level of the bottom of the conductive band of the third oxide semiconductor layer.
